(54) Title: SYSTEM AND METHOD FOR AUTOMATICALLY RECORDING TELEVISION PROGRAMS IN TELEVISION SYSTEMS WITH TUNERS EXTERNAL TO VIDEO RECORDERS

## (57) Abstract

A system capable of automatically recording television programs broadcast on different cable television channels. The system includes a cable box, a video recorder and a cable programmer. The consumer enters sets of channel, date, time-of-day and length commands ("CDTL information") or compressed codes representative of such sets of commands into the video recorder. From each set of commands, subsets of date, time-of-day and length ("DTL information") are stored in the video recorder's memory. At the same time or shortly thereafter, a subset of channel, date and time-of-day commands ("CDT information") from the same set of commands is transmitted to the cable programmer. The cable programmer and video recorder have independent control circuits to control certain aspects of the recording process according to the subsets of commands stored in their memories. The control circuits of the video recorder control the starting and stopping of recording while the control circuits of the cable programmer tune the channel on the cable box. Information is transferred from the video recorder to the cable programmer and from the cable programmer to the cable box via IR links or other remote control technique.

**SYSTEM AND METHOD FOR AUTOMATICALLY RECORDING  
TELEVISION PROGRAMS IN TELEVISION SYSTEMS  
WITH TUNERS EXTERNAL TO VIDEO RECORDERS**

**Field of the Invention**

15

This invention relates generally to video cassette recorder systems and particularly to an apparatus and method for using encoded information to shorten the time required to perform timer preprogramming and for remotely controlling various home electronic devices and for easily performing an initial setup routine of such an apparatus.

20

**Prior Art**

The video cassette recorder (VCR) has a number of uses, including playing back of tapes filmed by a video camera, playing back of pre-recorded tapes and recording and playing back of broadcast and cable television programs.

25

To record a television program in advance of viewing it, a two-step process is often used: (1) obtain the correct channel, date, time and length (CDTL) information from a television program guide, and (2) program this CDTL information into the VCR. Depending on the model, year and type of the VCR, the CDTL information can be programmed in various ways including: (i) pushing an appropriate sequence of keys in the console according to instructions contained in the user's manual, (ii) pushing an appropriate sequence of keys in a remote handheld control unit according to instructions contained in the user's manual (remote programming) and (iii) executing a series of keystrokes in the remote handheld control unit in response to a menu displayed on the television screen (on-screen programming). Other techniques for timer preprogramming have been suggested including: (iv) reading in certain bar code information using a light pen (light pen programming), and (v) entering instructions through a

30

35

1 computer or telephone modem. These various methods differ only in the  
physical means of specifying the information while the contents, being CDTL and  
certain power/clock/timer on-off commands are generally common although the  
detailed protocol can vary with different model VCRs. Methods (i) and (ii)  
5 described above can require up to 100 keystrokes, which has inhibited the free  
use of the timer preprogramming feature of VCRs. To alleviate this, new  
VCR models have included an "On-Screen Programming" feature, which permits  
remote input of CDTL information in response to a menu displayed on the  
television screen. Generally on screen programming of CDTL information  
10 requires an average of about 18 keystrokes, which is less than some of the prior  
methods but still rather substantial. Some of the other techniques such as (iv)  
above, require the use of special equipment such as a bar code reader.

In general the present state of the art suffers from a number of drawbacks.  
First, the procedure for setting the VCR to record in advance can be quite  
15 complex and confusing and difficult to learn; in fact, because of this many  
VCR owners shun using the timer preprogramming record feature. Second, the  
transcription of the CDTL information to the VCR is hardly ever error-free; in fact,  
many users of VCR's timer preprogramming features express concern over the  
high incidence of programming errors. Third, even for experienced users, the  
20 process of entering a lengthy sequence of information on the channel, date, time  
and length of desired program can become tedious. Fourth, techniques such as  
reading in bar code information or using a computer require special equipment.  
Fourth, many VCRs are not able to remotely change the channel on a cable box.  
Since many cable systems require the use of the cable system's cable box  
25 (decoder/tuner), this ability is needed in order to record programs on different  
cable channels. These drawbacks have created a serious impedance in the use  
of a VCR as a recording device for television programs. The effect is that time  
shifting of programs has not become as popular as it once was thought it would  
be. Accordingly, there is a need in the art for a simpler system for effecting  
30 VCR timer preprogramming which will enable a user to take advantage of the  
recording feature of a VCR more fully and freely.

#### Summary of the Invention

35 A principal feature of the invention is providing an improved system for the  
selection and entering of channel, date, time and length (CDTL) information  
required for timer preprogramming of a VCR which is substantially simpler, faster  
and less error-prone than present techniques. Another principal feature of the

1 invention is providing televisions having an embedded capability for timer programming control.

5 In accordance with the invention, to program the timer preprogramming feature of a video system, there is an apparatus and method for using encoded video recorder/player timer preprogramming information. The purpose is to significantly reduce the number of keystrokes required to set up the timer preprogramming feature on a VCR. In accordance with this invention it is only necessary for the user to enter a code with 1 to 8 digits or more into the VCR. This can be done either remotely or locally at the VCR. Built into either the 10 remote controller or the VCR is a decoding means which automatically converts the code into the proper CDTL programming information and activates the VCR to record a given television program with the corresponding channel, date, time and length. Generally multiple codes can be entered at one time for multiple program selections. The code can be printed in a television program guide in advance and selected for use with a VCR or remote controller with the decoding means. 15

A product embodying these features is now commercially available and has enjoyed great commercial success. This instant programmer, sold under the VCRPlus+ trademark, consists of a handheld unit into which compressed codes 20 (each 1 to 8 digits long) for television programs to be recorded are entered. The compressed codes are most commonly found in printed television listings. The instant programmer decodes the compressed codes into channel, date, time-of-day and length commands which are then stored in the programmer's memory. When date and time of the program in the memory that is scheduled the nearest to the current time coincides with the current time, as determined by 25 an internal clock, the instant programmer, using an infrared transmitter and universal remote technology, sends infrared remote control signals to a cable box or a video recorder to change the channel to the correct channel and infrared remote control signals to a video recorder to turn the recorder on and begin recording. After the length for the program, stored in memory, has elapsed, an 30 infrared remote control signal to stop recording is sent to the video recorder.

Before the VCRPlus+ programmer can be used, the user must perform an initial setup procedure. This procedure includes entering the brands and models of the user's video recorder and cable box into the programmer, setting the clock 35 in the programmer, and entering a local channel map which maps "national" channel numbers for certain networks and cable channels into the actual channel numbers used for these channel by the user's cable system. The instant

1 programmer is manufactured with the infrared codes necessary to remotely  
control a wide variety of cable boxes and video recorders stored in ROM. The  
model and brands of the cable box and video recorder must be entered so that  
the instant programmer will use the correct ones of the infrared codes stored in  
5 ROM for the user's particular video recorder and cable box.

In a parent application to the present application, an alternate embodiment  
is disclosed in which the decoder, memory and infrared transmitter of the instant  
programmer are embedded in a video recorder. The 1 to 8 digit compressed  
codes are entered directly into the video recorder, either through keys on the  
10 video recorder or through a remote for the video recorder. The compressed  
codes are decoded by the video recorder into channel, date, time-of-day and  
length commands and stored into the video recorder's memory. When the time  
and date of a program in memory coincides with the real time as supplied by the  
clock in the video recorder, the video recorder transmits, using its infrared  
15 transmitter and universal remote technology, infrared remote control signals to  
a cable box that change the channel tuned by the cable box to the desired  
channel. The video recorder then internally signals itself to begin recording the  
television signal received from the now correctly tuned cable box. When the  
length, stored in memory, has elapsed, the video recorder turns itself off.

20 Like with the VCRPlus+ Instant Programmer, before the video recorder  
with a built-in instant programmer and remote control transmitter can be used,  
an initial setup procedure must be performed. The brand and model of cable box  
and the local channel map must be manually entered into the video recorder.

The present invention includes an improvement to the video recorder with  
25 a built-in instant programmer and remote control transmitter. A system  
according to the invention is capable of automatically recording television  
programs broadcast on different cable or satellite television channels. The  
system includes a cable box (or satellite receiver), a video recorder and a cable  
programmer. A consumer enters sets of channel, date, time-of-day and length  
30 commands ("CDTL information") or compressed codes representative of such  
sets of commands into the video recorder. From each set of commands, subsets  
of date, time-of-day and length ("DTL information" or "recorder subsets") are  
stored in the video recorder's memory. At the same time or shortly thereafter,  
a subset of channel, date and time-of-day commands ("CDT information" or  
35 "cable subsets") from the same set of commands is transmitted to the cable  
programmer. The cable programmer and video recorder have independent control  
circuits to control certain aspects of the recording process according to the

1 subsets of commands stored in their memories. The control circuits of the video  
recorder control the starting and stopping of recording while the control circuits  
of the cable programmer tune the channel on the cable box. Information is  
transferred from the video recorder to the cable programmer and from the cable  
5 programmer to the cable box via IR links or other remote control technique.

Other objects and many of the attendant features of this invention will be  
more readily appreciated as the same becomes better understood by reference  
to the following detailed descriptions and considered in connection with the  
accompanying drawings in which like reference symbols designate like parts  
10 throughout the figures.

#### Brief Description of the Drawings

FIG. 1 is a schematic showing apparatus according to this invention with  
the code decoder means embedded in the video cassette recorder;

15 FIG. 2 is a schematic of the VCR embedded processors for command  
control and code decoding;

FIG. 3 is a schematic showing a preferred embodiment according to this  
invention with the code decoder means embedded in a remote controller;

FIG. 4 is a schematic of the processor embedded in the remote controller;

20 FIG. 5 is a schematic of a universal remote controller with the code  
decoder means embedded in the universal remote controller;

FIG. 6 is a flow graph of the G-code decoding technique;

FIG. 7 is a flow graph of the G-code encoding technique;

25 FIG. 8 is an illustration of part of a television calendar according to this  
invention;

FIG. 9 is a flowchart for decoding for cable channels;

FIG. 10 is a flowchart for encoding for cable channels;

30 FIG. 11 is a flow graph of the G-code decoding for cable channels  
including conversion from assigned cable channel number to local cable carrier  
channel number;

FIG. 12 is a means for decoding including a stack memory;

FIG. 13 is a flowchart for program entry into stack memory;

FIG. 14 is an operation flowchart for sending programs from remote  
control to main unit VCR;

35 FIG. 15 is a perspective view of an apparatus for using compressed codes  
for recorder preprogramming according to a preferred embodiment of the  
invention;

- 1           FIG. 16 is a front view of the apparatus of FIG. 15 showing a forward facing light emitting diode;
- FIG. 17 is a perspective view of the apparatus of FIG. 15 placed in a mounting stand;
- 5           FIG. 17A is a front elevational view of the apparatus of FIG. 15 placed in the mounting stand as shown in FIG. 17;
- FIG. 18 is a detail of the LCD display of the apparatus of FIG. 15;
- FIG. 19 is a perspective view showing a manner of placing the apparatus of FIG. 15 relative to a cable box and a VCR;
- 10          FIG. 20 is a perspective view showing a manner of placing the mounting stand with the apparatus of FIG. 15 mounted thereon near a cable box and VCR;
- FIG. 21 is a schematic showing apparatus for using compressed codes for recorder preprogramming according to a preferred embodiment of the invention;
- FIG. 22 is a detailed schematic showing a preferred embodiment of apparatus implementing the schematic of FIG. 21;
- 15          FIG. 23 is a flow graph for program entry into the apparatus of FIG. 15;
- FIG. 24 is a flow graph for review and program cancellation of programs entered into the apparatus of FIG. 15;
- FIG. 25 is a flow graph for executing recorder preprogramming using compressed codes according to a preferred embodiment of the invention;
- 20          FIG. 26 is a flow graph for encoding program channel, date, time and length information into decimal compressed codes;
- FIG. 27 is a flow graph for decoding decimal compressed codes into program channel, date, time and length information;
- 25          FIG. 28 is an embodiment of an assigned channel number/local channel number table;
- FIG. 29 is a block diagram of a system including a television having a G-code decoder;
- FIG. 30 is a schematic of a television having a G-code decoder;
- 30          FIG. 31 is a schematic showing apparatus for a G-code decoder in a television having G-code decoding;
- FIG. 32 is a block diagram of a system including a television having a G-code decoder, a VCR, a cable box and a satellite receiver;
- FIG. 33 is a block diagram of a system including a VCR having a G-code decoder, a television, a cable box and a satellite receiver;
- 35          FIG. 34 is a block diagram of a system including a cable box having a G-code decoder, a television, a VCR, and a satellite receiver;

1           FIG. 35 is a block diagram of a system including a satellite receiver having a G-code decoder, a television, a VCR and a cable box;

5           FIG. 36 is a perspective view showing a cable box placed on top of a VCR having an infrared transmitter behind the front panel which communicates to the cable box infrared receiver via reflection;

          FIG. 37 is a perspective view showing a cable box placed on top of a VCR having an infrared transmitter inside a infrared dome on the top of the VCR which communicates to the cable box infrared receiver;

10          FIG. 38 is a perspective view of a VCR having an infrared transmitter inside a mouse coupled via a cable to the VCR with the mouse placed near the cable box infrared receiver; and

          FIG. 39 is a perspective view of a VCR having an infrared transmitter inside a miniature mouse coupled via a cable to the VCR with the miniature mouse stuck onto the cable box near the infrared receiver.

15          FIG. 40 is a perspective view of a second apparatus for using compressed codes for recorder preprogramming according to a preferred embodiment of the invention.

          FIG. 41 is a bottom view of the apparatus of FIG. 41 showing a microphone hole and two electrical contact holes.

20          FIG. 42 shows the apparatus of FIG. 40 being used in conjunction with a telephone.

          FIG. 43 is a schematic showing second apparatus for using compressed codes for recorder preprogramming according to a preferred embodiment of the invention.

25          FIG. 44 is an alternate schematic showing second apparatus for using compressed codes for recorder preprogramming according to a preferred embodiment of the invention.

          FIG. 45 is a perspective view of an apparatus for programming remote controls with memories according to a preferred embodiment of the invention.

30          FIG. 46 is a perspective view of the apparatus of FIG. 45 with the hinged lid in the open position.

          FIG. 47 is a rear view of the apparatus of FIG. 45 showing telephone and computer input/output ports.

35          FIG. 48 is a bottom view of the apparatus of FIG. 15 showing electrical contact access holes.

          FIG. 49 is a perspective view of the apparatus of FIG. 45 coupled to an apparatus according to FIG. 15.

1           FIG. 50 is a perspective view of the apparatus of FIG. 45 coupled to an apparatus according to FIG. 40.

          FIG. 51 is a schematic showing apparatus for programming remote controls with memories according to a preferred embodiment of the invention.

5           FIG. 52 is a schematic showing the electronic connection between apparatus for programming remote controls with memories according to a preferred embodiment of the invention and a personal computer.

          FIG. 53 is a perspective view of a complete universal remote control capable of using compressed codes for recorder preprogramming according to a preferred embodiment of the invention.

10           FIG. 54 is a front view of the apparatus of FIG. 53.

          FIG. 55 is a side view of the apparatus of FIG. 53 showing a microphone opening and an electrical contact access hole.

          FIG. 56 is a rear view of the apparatus of FIG. 53.

15           FIG. 57 is a back view of the apparatus of FIG. 53 showing electrical contact access holes.

          FIG. 58 is a block schematic of an embodiment of the apparatus of FIG. 53.

          FIG. 59 is a block schematic of an alternative embodiment of the apparatus of FIG. 53.

20           FIG. 60 is a flowchart of the process of remotely programming the apparatus of FIG. 53 over telephone lines.

          FIG. 61 is a block diagram of a system for downloading initial setup data from a remote site, through a remote control, to a video recorder capable of controlling other devices, according to a preferred embodiment.

25           FIG. 62 is a flow diagram of a method for downloading initial setup data from a remote site, through a remote control, to a video recorder, according to a preferred embodiment.

          FIG. 63 is a block diagram for an alternative embodiment of the system shown in FIG. 61.

30           FIG. 64 is a block diagram for an alternative embodiment of the system shown in FIG. 61.

          FIG. 65 is a block diagram for an alternative embodiment of the system shown in FIG. 61.

35           FIG. 66 is a block diagram for a system for automatically recording cable television programs incorporating a cable programmer separate from a video recorder.

1           FIG. 67 is a block diagram for an alternative embodiment of the system shown in FIG. 66.

          FIG. 68 is a block diagram for an alternative embodiment of the system shown in FIG. 66.

5           FIG. 69 is a block diagram for an alternative embodiment of the system shown in FIG. 66.

#### Detailed Description

10           Referring now to the drawings, and more particularly, to FIG. 1, there is shown an apparatus for using encoded video recorder/player timer preprogramming information 10 according to this invention. The primary components include a remote controller 12 and a video cassette recorder/player with G-code decoder 14, which can be controlled by remote controller 12 via a command signal 16. The remote controller 12 can have a number of keys, which  
15           include numerical keys 20, G-code switch 22, function keys 24, program key 26 and power key 27. There are means in the remote controller 12 that interprets each key as it is pressed and sends the proper command signal 16 to the VCR via an infrared light emitting diode 28. Except for the G-code switch 22 on the remote controller 12 in FIG. 1, the remote controller 12 is essentially the same  
20           as any other remote controller in function. The G-code switch 22 is provided just to allow the user to lock the remote controller 12 in the G-code mode while using a G-code, which is the name given to the compressed code which is the encoded CDTL information, to perform timer preprogramming.

25           A G-code consists of 1 to 7 digits, although more could be used, and is associated with a particular program. A user would look up the G-code in a program guide and just enter the G-code on the remote controller 12, instead of the present state of the art, which requires that the user enter the actual channel, date, time and length (CDTL) commands.

30           In order to understand the advantages of using a G-code, it is helpful to describe the best of the current state of the art, which is "on screen programming" with direct numerical entry. This technique involves about 18 keystrokes and the user has to keep switching his view back and forth between the TV screen and the remote controller while entering the CDTL information. This situation may be akin to a user having to dial an 18 digit  
35           telephone number while reading it from a phone book. The number of keys involved and the switching back and forth of the eye tend to induce errors. A

1 typical keying sequence for timer recording using on-screen CDTL programming  
is as follows:

PROG 2 1 15 07 30 2 08 00 2 04 PROG

5

The first program (PROG) key 26 enters the programming mode. Then a sequence of numerical keys 20 are pushed. The 2 means it is timer recording rather than time setting. The 1 means the user is now entering the settings for program 1. The 15 is the date. The 07 is starting hour. The 30 is a starting  
10 minute. The 2 means pm. The next sequence 08 00 2 is the stopping time. The 04 is channel number. Finally, the PROG is hit again to exit the program mode.

By contrast, this command could have been "coded" and entered in a typical G-code sequence as follows: PROG 1138 PROG. To distinguish that the  
15 command is a coded G-code, the G-code switch 22 should be turned to the "ON" position. Instead of having a switch, a separate key "G" can be used. The G-code programming keystroke sequence would then be: G 1138 PROG.

The use of a G-code does not preclude "on-screen" confirmation of the program information that has been entered. When the keystrokes "PROG 1138  
20 PROG" are entered with the G-code switch in the "ON" position, the G-code would be decoded and the television could display the following message:

PROGRAM	DATE	START TIME	STOP TIME	CHANNEL
1138	15	7:30 PM	8:00 PM	4

25

In order for the G-code to be useful it must be decoded and apparatus for that purpose must be provided. Referring to FIG. 1, a video cassette recorder/player with G-code decoder 14 is provided to be used in conjunction with remote controller 12. The command signal 16 sent from the remote  
30 controller 12 is sensed by the photodiode 32 and converted to electrical signals by command signal receiver 30. The electrical signals are sent to a command controller 36, which interprets the commands and determines how to respond to the commands. As shown in FIG. 1, it is also possible for the command controller 36 to receive commands from the manual controls 34 that are normally  
35 built into a VCR. If the command controller 36 determines that a G-code was received then the G-code will be sent to the G-code decoder 38 for decoding. The G-code decoder 38 converts the G-code into CDTL information, which is

1        used by the command controller 36 to set the time/channel programming 40.  
Built into the VCR is a clock 42. This is normally provided in a VCR and is used  
to keep track of the date and time. The clock 42 is used primarily by the  
time/channel programming 40 and the G-code decoder 38 functions. The  
5        time/channel programming 40 function is set up with CDTL information by the  
command controller 36. When the proper date and time is read from clock 42,  
then the time/channel programming 40 function turns the record/playback 44  
function "ON" to record. At the same time the tuner 46 is tuned to the proper  
channel in the television signal 18. Later the user can command the  
10        record/playback 44 function to a playback mode to watch the program via the  
television monitor 48.

      An alternate way to control the recorder is to have the command  
controller 36 keep all the CDTL information instead of sending it to the  
time/channel programming 40. The command controller would also keep track  
15        of the time by periodically reading clock 42. The command controller would then  
send commands to the time/channel programming 40 to turn on and off the  
recorder and to tuner 46 to cause it to tune to the right channel at the right time  
according to the CDTL information.

      The clock 42 is also an input to G-code decoder 38, which allows the  
20        G-code decoding to be a function of the clock, which lends a measure of security  
to the decoding technique and makes it harder to copy. Of course this requires  
that the encoding technique must also be a function of the clock.

      A possible realization of the command controller 36 and the G-code  
decoder 38 is shown in FIG. 2. The command controller 36 function can be  
25        realized with a microprocessor 50, a random access memory 52 and a read only  
memory 54, which is used for program storage. The input/output 56 function  
is adapted to receive commands from the command signal receiver 30, the  
manual controls 34 and the clock 42, and to output signals to a display 35, the  
clock 42, and the time/channel programming 40 function. If the microprocessor  
30        50 interprets that a G-code has been received, then the G-code is sent to  
microcontroller 60 for decoding. The microcontroller 60 has an embedded  
random access memory 62 and an embedded read only memory 64 for program  
and table storage. The clock 42 can be read by both microprocessor 50 and  
microcontroller 60.

35        An alternative to having microcontroller 60 perform the G-code decoding  
is to build the G-code decoding directly into the program stored in read only  
memory 54. This would eliminate the need for microcontroller 60. Of course,

1        other hardware to perform the G-code decoding can also be used. The choice of which implementation to use is primarily an economic one.

         The blocks in FIGS. 1 and 2 are well known in the prior art and are present in the following patents: Fields, Patent No. 4,481,412; Scholz, Patent  
5        No. 4,519,003; and Brugliera, Patent No. 4,631,601. For example, clock 42 is analogous to element 7 in Scholz and element 17 in Brugliera. Other analogous elements are: command signal receiver 30 and Scholz 14 and Brugliera 12;  
10        tuner 46 and Scholz 6 and Brugliera 10; time/channel programming 40 and Scholz 8, 11 and Brugliera 16; record & playback 44 and Scholz 1, 2, 4;  
15        command controller 36 and Scholz 11, 10 and Brugliera 12; microprocessor 50 and Fields 27; RAM 52 and Fields 34; ROM 54 and Fields 33; manual controls 34 and Scholz 15, 16; and remote controller 12 and Scholz 26 and Brugliera 18.

         FIG. 3 illustrates an alternate preferred embodiment of this invention. In FIG. 3 a remote controller with embedded G-code decoder 80 is provided. The  
15        remote controller with embedded G-code decoder 80 is very similar to remote controller 12, except for the addition of the G-code decoder 82. Note that it is also possible in any remote controller to provide a display 84. The remote controller with embedded G-code decoder 80 would be used in conjunction with  
20        a normal video cassette recorder/player 70, which would not be required to have an embedded G-code decoder. The numerals for the subelements of video cassette recorder/player 70 are the same as described above for the video cassette recorder/player with G-code decoder 14 and have the same function, except for the absence of G-code decoder 38. This preferred embodiment has the advantage that it can be used in conjunction with VCRs that are presently  
25        being used. These do not have a G-code decoding capability. Replacing their remote controllers with ones that have this capability built in can vastly improve the capability to do timer preprogramming for a modest cost.

         FIG. 4 illustrates a possible realization of the G-code decoder 82 built into the remote controller with embedded G-code decoder 80. A microcontroller 60  
30        can be used as before to decode the G-code, as well as interface with the display 84, a clock 85, the keypad 88 and the light emitting diode 28. Alternately, other hardware implementations can be used to perform the G-code decoding. The clock 85 is provided in the remote controller 80 so that the G-code decoder 82 can be made to have the clock 85 as one of its inputs. This  
35        allows the G-code decoding to be a function of the clock 85, which lends a measure of security to the decoding technique and makes it harder to copy.

1           The remote controller with embedded G-code decoder as described above  
would send channel, date, time and length information to the video cassette  
recorder/player 70, which would use the CDTL information for tuning into the  
correct channel and starting and stopping the recording function. The remote  
5       controller may have to be unique for each different video cassette  
recorder/player, because each brand or model may have different infrared pulses  
for each type of information sent such as the channel number keys and start  
record and stop record keys. The particular infrared pulses used for each key  
type can be called the vocabulary of the particular remote controller. Each model  
10       may also have a different protocol or order of keys that need to be pushed to  
accomplish a function such as timer preprogramming. The protocol or order of  
keys to accomplish a function can be called sentence structure. If there is a  
unique remote controller built for each model type, then the proper vocabulary  
and sentence structure can be built directly into the remote controller.

15           An alternate to having the remote controller with embedded G-code  
decoder send channel, date, time and length information to the video cassette  
recorder/player 70, is to have the remote controller with embedded G-code  
decoder perform more operations to simplify the interfacing problem with existing  
video cassette recorder/players. In particular, if the remote controller not only  
20       performs the G-code decoding to CDTL, but also keeps track of time via  
clock 85, then it is possible for the remote controller to send just channel, start  
record and stop commands to the video cassette recorder/player. The channel,  
start and stop are usually basic one or two key commands, which means there  
is no complicated protocol or sentence structure involved. Thus, to  
25       communicate with a diverse set of video cassette recorder/player models it is  
only necessary to have memory within the remote controller, such as ROM 64  
of FIG. 4, for storing the protocol for all the models or at least a large subset.  
The G-code would be entered on the remote controller as before and decoded  
into channel, date, time and length information, which would be stored in the  
30       remote controller. Via clock 85, the time would be checked and when the  
correct time arrives the remote controller would automatically send out  
commands to the VCR unit for tuning to the correct channel and for starting and  
stopping the recording. It is estimated that only two (2) bytes per key for about  
15 keys need to be stored for the vocabulary for each video cassette  
35       recorder/player model. Thus, to cover 50 models would only require about  
 $30 \times 50 = 1500$  bytes of memory in the remote controller. It would be necessary

1       to position the remote controller properly with respect to the VCR unit so that the infrared signals sent by the remote controller are received by the unit.

Another preferred embodiment is to provide a universal remote controller 90 with an embedded G-code decoder. Universal remote controllers provide the  
5       capability to mimic a number of different remote controllers. This reduces the number of remote controllers that a user needs to have. This is accomplished by having a learn function key 94 function on the universal remote controller, as shown in FIG. 5. If the learn function key 94 is pushed in conjunction with another key, the unit will enter into the learn mode. Incoming infrared (IR) pulses  
10       from the remote controller to be learned are detected by the infrared photodiode 96, filtered and wave-shaped into recognizable bit patterns before being recorded by a microcontroller into a battery-backed static RAM as the particular IR pulse pattern for that particular key. This is done for all the individual keys.

An example of more complex learning is the following. If the learn  
15       function key 94 in conjunction with the program key 26 are pushed when the G-code switch is "ON", the unit will recognize that it is about to record the keying sequence of a predetermined specific example of timer preprogramming of the particular VCR involved. The user will then enter the keying sequence from which the universal remote controller 90 can then deduce and record the  
20       protocol of the timer preprogramming sequence. This is necessary because different VCRs may have different timer preprogramming command formats.

If keys are pushed without the learn function key 94 involved, the microcontroller should recognize it is now in the execute mode. If the key is one of the direct command keys, the microcontroller will read back from its static  
25       RAM the stored pulse sequence and send out command words through the output parallel I/O to pulse the output light emitting diode 28. If the key is the PROG key and the G-code switch is "OFF", then the microcontroller should recognize the following keys up to the next PROG key as a timer preprogramming CDTL command and send it out through the light emitting diode 28. If the  
30       G-code switch 22 is set to "ON" and the program key 26 is pushed, the microcontroller should recognize the following keys up to the next PROG key as a G-code command for timer preprogramming. It will decode the G-code into channel, date, start time and length (CDTL) and the microcontroller will then look up in it's static RAM "dictionary" the associated infrared pulse patterns and concatenate them together before sending them off through the output parallel  
35       I/O to pulse the light emitting diode 28 to send the whole message in one continuous stream to the VCR.

1           FIG. 4 illustrates a possible realization of the G-code decoder 92 that could  
be built into the universal remote controller with embedded G-code decoder 90.  
A microcontroller 60 can be used as before to decode the G-code, as well as for  
interfacing with the input/output functions including the photodiode 96.  
5           Alternately, the G-code decoding can be performed with other hardware  
implementations.

          The universal remote controller can also be used in another manner to  
simplify the interfacing problem with existing video cassette recorder/players.  
In particular, if the universal remote controller performs not only the G-code  
10          decoding to CDTL, but also keeps track of time via clock 85 in FIG. 4, then it is  
possible for the universal remote controller to send just channel, start record and  
stop commands to the video cassette recorder/player, which as explained before,  
are usually basic one key commands, which means there is no complicated  
protocol or sentence structure involved. Thus, to communicate with a diverse  
15          set of video cassette recorder/player models it is only necessary for the universal  
remote controller to "learn" each key of the remote controller it is replacing. The  
G-code would be entered on the universal remote controller as before and  
decoded into channel, date, time and length information, which would be stored  
in the universal remote controller. Via clock 85, the time would be checked and  
20          when the correct time arrives the universal remote controller would automatically  
send out commands to the VCR unit for tuning to the correct channel and for  
starting and stopping the recording. It would be necessary to position the  
universal remote controller properly with respect to the VCR unit so that the  
signals sent by the universal remote are received by the VCR unit.

25          There are a number of ways that the G-code decoding can be performed.  
The most obvious way is to just have a large look-up table. The G-code would  
be the index. Unfortunately, this would be very inefficient and result in a very  
expensive decoder due to the memory involved. The total storage involved is a  
function of the number of total combinations. If we allow for 128 channels,  
30          31 days in a month, 48 on the hour and on the half hour start times in a twenty  
four hour day, and 16 length selections in half hour increments, then the total  
number of combinations is  $128 \times 31 \times 48 \times 16 = 3,047,424$ . This number of  
combinations can be represented by a 7 digit number. The address to the table  
would be the 7 digit number. In the worst case, this requires a look-up table that  
35          has about 4,000,000 rows by 15 to 16 digital columns, depending on the  
particular protocol. These digital columns would correspond to the CDTL  
information required for "on screen programming". Each digit could be

1 represented by a 4 bit binary number. Thus, the total storage number of bits  
 required for the look-up table would be about  $4,000,000 \times 16 \times 4 = 256,000,000$ .  
 The present state of the art has about 1 million bits per chip. Thus, G-code  
 decoding using a straightforward table look up would require a prohibitively  
 5 expensive number of chips.

Fortunately, there are much more clever ways of performing the G-code  
 decoding. FIG. 6 is a flow diagram of a preferred G-code decoding technique.  
 To understand G-code decoding, it is easiest to first explain the G-code encoding  
 technique, for which FIG. 7 is the flowchart. Then the G-code decoding  
 10 technique, which is the reverse of the G-code encoding will be explained.

The encoding of the G-codes can be done on any computer and is done  
 prior to preparation of any program guide that would include G-codes. For each  
 program that will be printed in the guide, a channel, date, time and length (CDTL)  
 code 144 is entered in step 142. Step 146 separately reads the priority for the  
 15 channel, date, time and length in the priority vector storage 122, which can be  
 stored in read only memory 64. The priority vector storage 122 contains four  
 tables: a priority vector C table 124, a priority vector D table 126, a priority  
 vector T table 128 and a priority vector L table 130.

The channel priority table is ordered so that the most frequently used  
 20 channels have a low priority number. An example of the data that is in priority  
 vector C table 124 follows.

channel	4	7	2	3	5	6	11	13	...
priority	0	1	2	3	4	5	6	7	...

25

Generally the dates of a month all have an equal priority, so the low  
 number days in a month and the low number priorities would correspond in the  
 priority vector D table as in the following example.

date	1	2	3	4	5	6	7	8	...
priority	0	1	2	3	4	5	6	7	...

30

35

1           The priority of the start times would be arranged so that prime time would have a low priority number and programs in the dead of the night would have a high priority number. For example, the priority vector T table would contain:

5	time	6:30pm	7:00pm	8:00pm	7:30pm	...
	priority	0	1	2	3	...

An example of the data that is in the priority vector L table 130 is the following:

10	length of program (hours)	0.5	1.0	2.0	1.5	3.0	...
	priority	0	1	2	3	4	...

Suppose the channel date time length (CDTL) 144 data is 5 10 19.00 1.5, which means channel 5, 10th day of the month, 7:00 PM, and 1.5 hours in length, then for the above example the  $C_p, D_p, T_p, L_p$  data 148, which are the result of looking up the priorities for channel, date, time and length in priority tables 124, 126, 128 and 130 of FIG. 7, would be 4 9 1 3. Step 150 converts  $C_p, D_p, T_p, L_p$  data to binary numbers. The number of binary bits in each conversion is determined by the number of combinations involved. Seven bits for  $C_p$ , which can be denoted as  $C_7 C_6 C_5 C_4 C_3 C_2 C_1$ , would provide for 128 channels. Five bits for  $D_p$ , which can be denoted as  $D_5 D_4 D_3 D_2 D_1$ , would provide for 31 days in a month. Six bits for  $T_p$ , which can be denoted as  $T_6 T_5 T_4 T_3 T_2 T_1$ , would provide for 48 start times on each half hour of a twenty four hour day. Four bits for length, which can be denoted as  $L_4 L_3 L_2 L_1$ , would provide for a program length of up to 8 hours in half hour steps. Together there are  $7 + 5 + 6 + 4 = 22$  bits of information, which correspond to  $2^{22} = 4,194,304$  combinations.

The next step is to use bit hierarchy key 120, which can be stored in read only memory 64 to reorder the 22 bits. The bit hierarchy key 120 can be any ordering of the 22 bits. For example, the bit hierarchy key might be:

$L_8$	$C_3$	...	$T_2$	$C_2$	$T_1$	$C_1$	$L_1$	$D_5$	$D_4$	$D_3$	$D_2$	$D_1$
22	21	...	10	9	8	7	6	5	4	3	2	1

Ideally the bit hierarchy key is ordered so that programs most likely to be the subject of timer preprogramming would have a low value binary number, which would eliminate keystrokes for timer preprogramming the most popular

1 programs. Since all the date information has equal priority, then the  $D_5 D_4 D_3 D_2$   
 $D_1$  bits are first. Next  $T_1 C_1 L_1$  are used, because for whatever date it is  
 5 necessary to have a time channel and length and  $T_1 C_1 L_1$  are the most probable  
 in each case due to the ordering of the priority vectors in priority vector  
 storage 122. The next bit in the hierarchy key is determined by the differential  
 probabilities of the various combinations. One must know the probabilities of all  
 the channels, times and lengths for this calculation to be performed.

For example, the probability for channels may be:

10	channel	4	7	2	3	5	6	11	13	...
	priority	0	1	2	3	4	5	6	7	...
	probability(%)	5	4.3	4	3	2.9	2.1	2	1.8	...

The probabilities for times might be:

15	time	6:30pm	7:00pm	8:00pm	7:30pm	...
	priority	0	1	2	3	...
	probability(%)	8	7.8	6	5	...

20 And, the probabilities for lengths might be:

	length of program (hours)	0.5	1.0	2.0	1.5	3.0	...
	priority	0	1	2	3	4	...
	probability(%)	50	20	15	5	4	...

25 The probabilities associated with each channel, time and length, as  
 illustrated above, are used to determine the proper ordering. Since the priority  
 vector tables are already ordered by the most popular channel, time, and length,  
 the order in which to select between the various binary bits for one table, for  
 30 example selecting between the  $C_7 C_6 C_5 C_4 C_3 C_2 C_1$  bits, is already known. The  
 $C_1$  bit would be selected first because as the lowest order binary bit it would  
 select between the first two entries in the channel priority table. Then the  $C_2$  bit  
 would be selected and so on. Similarly, the  $T_1$  and  $L_1$  bits would be used before  
 any of the other time and length bits. A combination of the  $C_1$ ,  $T_1$ ,  $L_1$  and  
 35  $D_5 D_4 D_3 D_2 D_1$  bits should be used first, so that all the information is available  
 for a channel, date, time and length. The  $D_5 D_4 D_3 D_2 D_1$  bits are all used

1 because the date bits all have equal priority and all are needed to specify a date even if some of the bits are binary zero.

At this point the bit hierarchy key could be:

5  $T_1 C_1 L_1 D_5 D_4 D_3 D_2 D_1$

The first channel binary bit  $C_1$  by itself can only select between  $2^1 = 2$  channels, and the first two channels have a probability percent of 5 and 4.3, respectively. So the differential probability of  $C_1$  is 9.3. Similarly, the differential probability of  $T_1$  is  $8 + 7.8 = 15.8$ , and the differential probability of  $L_1$  is  $50 + 20 = 70$ . If the rules for ordering the bit hierarchy key are strictly followed, then the first 8 bits of the bit hierarchy key should be ordered as:

15  $C_1 T_1 L_1 D_5 D_4 D_3 D_2 D_1$

because  $L_1$  has the highest differential priority so it should be the next most significant bit after  $D_5$ , followed by  $T_1$  as the next most significant bit, and then  $C_1$  as the next most significant bit. Notice that the bit hierarchy key starts with the least significant bit  $D_1$ , and then is filled in with the highest differential probability bits. This is for the purpose of constructing the most compact codes for popular programs.

The question at this point in the encoding process is what should the next most significant bit in the hierarchy key be:  $T_2$ ,  $C_2$ , or  $L_2$ . This is again determined by the differential probabilities, which can be calculated from the above tables for each bit. Since we are dealing with binary bits, the  $C_2$  in combination with  $C_1$  selects between  $2^2 = 4$  channels or 2 more channels over  $C_1$  alone. The differential probability for  $C_2$  is then the additional probabilities of these two additional channels and for the example this is:  $4 + 3 = 7$ . In a similar manner  $C_3$  in combination with  $C_1$  and  $C_2$  selects between  $2^3 = 8$  channels or  $4 = 2^{(3-1)}$  more channels over the combination of  $C_1$  and  $C_2$ . So the differential probability of  $C_3$  is the additional probabilities of these four additional channels and for the example this is:  $2.9 + 2.1 + 2 + 1.8 = 8.8$ . In a similar manner, the differential probabilities of  $T_2$  and  $L_2$  can be calculated to be  $6 + 5 = 11$  and  $15 + 5 = 20$ , respectively. Once all the differential probabilities are calculated, the next step is determining which combinations of bits are more probable.

1           Now for the above example, which combination is more probable:  $T_2$  with  $C_1$ ,  $L_1$ , or  $C_2$  with  $T_1$ ,  $L_1$ , or  $L_2$  with  $T_1$ ,  $C_1$ . This will determine the next bit in the key. So, which is greater:  $11 \times 9.3 \times 70 = 7161$ ;  $7 \times 15.8 \times 70 = 7742$ ; or  $20 \times 15.8 \times 9.3 = 2938.8$ ? In this case the combination with the greatest probability is  $7 \times 15.8 \times 70 = 7742$ , which corresponds to  $C_2$  with  $T_1$ ,  $L_1$ . So,  $C_2$  is selected as the next bit in the bit hierarchy key.

5           The next bit is selected in the same way. Which combination is more probable:  $C_3$  with  $T_1$ ,  $L_1$ , or  $T_2$  with  $C_1$  or  $C_2$  and  $L_1$ , or  $L_2$  with  $C_1$  or  $C_2$  and  $T_1$ . For the example shown, which has the greatest probability:  $8.8 \times 15.8 \times 70 = 9732.8$ ;  $11 \times (9.3 + 7) \times 70 = 12551$ ; or  $20 \times (9.3 + 7) \times 15.8 = 5150.8$ ? In this case the combination with the greatest probability is  $11 \times (9.3 + 7) \times 70 = 12551$ , which corresponds  $T_2$  with  $C_1$  or  $C_2$  and  $L_1$ . So,  $T_2$  is selected as the next bit in the bit hierarchy key. This procedure is repeated for all the differential probabilities until the entire key is found.

15           Alternately, the bit hierarchy key can be just some arbitrary sequence of the bits. It is also possible to make the priority vectors interdependent, such as making the length priority vector dependent on different groups of channels. Another technique is to make the bit hierarchy key 120 and the priority vector tables 122, a function of clock 42, as shown in FIG. 7. This makes it very difficult for the key and therefore the coding technique to be duplicated or copied.

20           For example it is possible to scramble the date bits in the bit hierarchy key 120 as a function of the clock. Changing the order of the bits as a function of the clock would not change the effectiveness of the bit hierarchy key in reducing the number of binary bits for the most popular programs, because the date bits all are of equal priority. This could be as simple as switching the  $D_1$  and  $D_5$  bits periodically, such as every day or week. Thus the bit hierarchy key 120 would switch between

30                           ...      $C_1 T_1 L_1 D_5 D_4 D_3 D_2 D_1$   
and  
                              ...      $C_1 T_1 L_1 D_1 D_4 D_3 D_2 D_5$

35           Clearly other permutations of the bit hierarchy key as a function of the clock are possible.

          The priority vector tables could also be scrambled as a function of the clock. For example, the first two channels in the priority channel table could just

1 be swapped periodically. If this technique is followed, then the  $C_p$  of 148 in FIG. 7 would change as a function of the clock 42. For example,

5	channel	4	7	2	3	5	6	11	13	...
	priority	0	1	2	3	4	5	6	7	...

would change periodically to:

10	channel	7	4	2	3	5	6	11	13	...
	priority	0	1	2	3	4	5	6	7	...

15 This would be a fairly subtle security technique, because a decoder that was otherwise correct would only fail if those first two channels were being used. Other clock dependencies are also possible to provide security for the coding technique.

However it is derived, the bit hierarchy key 120 is determined and stored. In step 154 the binary bits of  $C_p, D_p, T_p, L_p$  are rearranged according to the bit hierarchy key 120 to create one 22 bit binary number. Then the resulting 22 bit binary number is converted to decimal in the convert binary number to decimal G-code step 156. The result is G-code 158.

If the priority vector and the bit hierarchy key are well matched to the viewing habits of the general population, then it is expected that the more popular programs would require no more than 3 or 4 digits for the G-code.

25 Now that the encoding technique has been explained the decoding technique is just reversing the coding technique. This is done according to the flowchart of FIG. 6. This is the preferred G-code decoding that can be built into G-code decoder 38 in VCR 14 or the remote controller G-code decoders 82 and 92 in FIGS. 3 and 5.

30 The first step 102 is to enter G-code 104. Next the G-code 104 is converted to a 22 bit binary number in step 106. Then the bits are reordered in step 108 according to the bit hierarchy key 120 to obtain the reordered bits 110. Then the bits are grouped together and converted to decimal form in step 112. As this point we obtain  $C_p, D_p, T_p, L_p$  data 114, which are the indices to the priority vector tables. For the above example, we would have at this step the vector 4 9 1 3. This  $C_p, D_p, T_p, L_p$  data 114 is then used in step 116 to look up channel, date, time, and length in priority vector storage 122. The CDTL 118 for

1       the example above is 5 10 19.00 1.5, which means channel 5, 10th day of the month, 7:00 PM, and 1.5 hours in length.

5       If the coding technique is a function of the clock then it is also necessary to make the decoding technique a function of the clock. It is possible to make the bit hierarchy key 120 and the priority vector tables 122, a function of clock 42, as shown in FIG. 6. This again makes it very difficult for the key and therefore the coding technique to be duplicated or copied. It is also possible to have the decoding and encoding techniques dependent on any other predetermined or preprogrammable algorithm.

10       Although the above G-code encoding and decoding technique is a preferred embodiment, it should be understood that there are many ways to perform the intent of the invention which is to reduce the number of keystrokes required for timer preprogramming. To accomplish this goal there are many ways to perform the G-code encoding and decoding. There are also many ways to make the encoding and decoding technique more secure besides just making the encoding and decoding a function of the clock. This security can be the result of any predetermined or preprogrammed algorithm.

15       It is possible in the G-code coding and decoding techniques to use mixed radix number systems instead of binary numbers. For example, suppose that there are only 35 channels, which would require 6 binary bits to be represented; however, 6 binary bits can represent 64 channels, because  $2^6 = 64$ . The result is that in a binary number system there are 29 unnecessary positions. This can have the effect of possibly making a particular G-code longer than it really needs to be. A mixed radix number system can avoid this result. For example, for the case of 35 channels, a mixed radix number system with the factors of  $7^1$  and  $5^0$  can represent 35 combinations without any empty space in the code. The allowed numbers for the  $7^1$  factor are 0, 1, 2, 3, and 4. The allowed numbers for the  $5^0$  factor are 0, 1, 2, 3, 4, 5, and 6. For example, digital 0 is represented in the mixed radix number system as 00. The digital number 34 is represented in the mixed radix number system as 46, because  $4 * 7^1 + 6 * 5^0 = 34$ . The major advantage of a mixed radix number system is in prioritizing the hierarchy key. If the first 5 channels have about equal priority and the next 30 are also about equal, then the mixed radix number system allows the two tiers to be accurately represented. This is not to say that a mixed radix number system is necessarily preferable. Binary numbers are easier to represent in a computer and use of a fixed radix number system such as binary numbers allows a pyramid of prioritization to be easily represented in the hierarchy key.

1           Another feature that is desirable in all of the embodiments is the capability  
to key in the G-code once for a program and then have the resulting CDTL  
information used daily or weekly. Ordinarily the CDTL information is discarded  
once it is used. In the case of daily or weekly recording of the same program,  
5           the CDTL information is stored and used until it is cancelled. The desire to  
repeat the program daily or weekly can be performed by having a "WEEKLY" or  
"DAILY" button on the remote controller or built into the VCR manual controls.  
Another way is to use one key, such as the PROG key and push it multiple times  
within a certain period of time such as twice to specify daily or thrice to specify  
10          weekly. For example, if the G-code switch is "ON" and the G-code for the  
desired program is 99 then daily recording of the program can be selected by the  
following keystrokes:

                  "PROG 99 DAILY PROG"  
15          or by:  
                  "PROG 99 PROG PROG"

                  The G-code 99 would be converted to CDTL information, which would be stored  
and used daily in this case. The recording would begin on the date specified and  
20          continue daily after that using the same channel time and length information. A  
slight twist is that daily recording could be automatically suspended during the  
weekends, because most daily programs are different on Saturday and Sunday.

                  Once a daily or weekly program is set up, then it can be used indefinitely.  
If it is desired to cancel a program and if there is a "CANCEL" button on the  
25          remote controller or manual control for the VCR, then one way to cancel a  
program (whether it is a normal CDTL, daily or weekly entry) is to key in the  
following:

                  "PROG xx CANCEL", where xx is the G-code  
30

                  Again as before there are alternate ways of accomplishing this.

                  If "on screen programming" is available, then the programs that have been  
selected for timer preprogramming could be reviewed on the screen. The daily  
and weekly programs would have an indication of their type. Also the G-codes  
35          could be displayed along with the corresponding CDTL information. This would  
make it quite easy to review the current "menu" and either add more programs  
or cancel programs as desired.

1 A television calendar 200 according to this invention is illustrated in  
FIG. 8. As shown, the television calendar has multiple day of year sections 202,  
multiple day sections 204, multiple time of day sections 206, channel identifiers  
208, and descriptive program identifiers 210, including the name of the program,  
5 arranged in a manner that is common in television guide publications. Arranged  
in relation to each channel identifier is a compressed code indication 212 or  
G-code containing the channel, date, time and length information for that entry  
in the television calendar. FIG. 8 shows how easy it is to perform timer  
programming. All one needs to do is find the program one wants to watch and  
10 enter the compressed code shown in the compressed code indication. This is in  
contrast to having to deal with all the channel, date, time and length entries  
separately. At least the channel, date and time are explicitly stated in the  
television guide. The length is usually only available by searching the guide to  
find the time of day section 206 where a new program begins and then  
15 performing some arithmetic to find the length of the program. Using the  
compressed G-code avoids all these complications.

For cable television programs, there is an additional issue that needs to be  
addressed for the compressed G-code to be useful. In a normal television guide,  
CDTL information is available for all the normal broadcast channels in the form  
20 of numbers including the channel numbers, such as channel 4 or 7. However,  
for cable channels like HBO, ESPN etc., only the names of the channels are  
provided in most television listings. The reason for this is that in some  
metropolitan areas, such as Los Angeles, there may be only one (1) edition of  
television guide, but there may be quite a few cable carriers, each of which may  
25 assign HBO or ESPN to different cable channel numbers. In order for a  
compressed code such as the G-code to be applicable to the cable channels as  
published by a wide area television guide publication, the following approach can  
be used.

First, all the cable channels would be permanently assigned a unique  
30 number, which would be valid across the nation. For example, we could assign  
ESPN to cable channel 1, HBO as cable channel 2, SHO as cable channel 3, etc.  
This assignment would be published by the television guide publications.

The video cassette recorder apparatus, such as the remote controller, the  
VCR unit or both, could then be provided with two (2) extra modes: "set" and  
35 "cable channel". One way of providing the user interface to these modes would  
be to provide two (2) extra buttons: one called SET and one called CABLE  
CHANNEL. The buttons could be located on the video cassette recorder unit

1 itself or located on a remote controller, as shown in FIGS. 1, 3 and 5, where SET is element 168 and CABLE CHANNEL is element 170. Of course, other user interfaces are possible.

5 Next, the television viewer would have to go through a one-time "setting" procedure of his VCR for all the cable channels that he would likely watch. This "setting" procedure would relate each of the assigned numbers for each cable channel to the channel number of the local cable carrier. For example, suppose that the local cable carrier uses channel 6 for ESPN, then cable channel number 1 could be assigned to ESPN, as shown in the following table.

10

<u>Cable Channel</u>	<u>Assigned</u>	<u>Channel Number in</u>
<u>Name</u>	<u>Cable Chan. No.</u>	<u>the Local Cable Carrier</u>
ESPN	1	6
HBO	2	24
15 SHO	3	23
.	.	.
.	.	.
.	.	.
DIS	8	25

20

The user could perform the "setting" procedure by pushing the buttons on his remote controller as follows:

25 SET 06 CABLE CHANNEL 1 PROGRAM  
 SET 24 CABLE CHANNEL 2 PROGRAM  
 SET 23 CABLE CHANNEL 3 PROGRAM  
 SET 25 CABLE CHANNEL 8 PROGRAM

30 The "setting" procedure would create a cable channel address table 162, which would be loaded into RAM 52 of command controller 36. For the above

35

1 example, the cable channel address table 162 would have the following information.

CABLE CHANNEL ADDRESS TABLE 162

5	1	6
	2	24
	3	23
	.	.
	.	.
10	.	.
	8	25

After the "setting" procedure is performed, the TV viewer can now select cable channels for viewing by the old way: e.g., pushing the key pad buttons 24 will select HBO. He can also do it the new way: e.g., by pushing CABLE CHANNEL 2, which will also select HBO. The advantage of the new way is that the television guide will publish [C2] next to the program description, so the viewer will just look up the assigned channel number identifier instead of having to remember that HBO is local cable channel 24. When the CABLE CHANNEL button is pushed, command controller 36 knows that it will look up the local cable channel number in cable channel address table 162 to tune the VCR to the correct channel.

For timer preprogramming and for using the compressed G-code, a way to differentiate between broadcast and cable channels is to add an eighth channel bit, which would be set to 0 for normal broadcast channels and 1 for cable channels such as HBO. This eighth channel bit could be one of the low order bits such as the third bit  $C_3$  out of the eight channel bits, so that the number of bits to specify popular channels is minimized, whether they be normal broadcast or cable channels. For a normal broadcast channel, the 7 other bits can be decoded according to priority vector C table 124. For a cable channel, the 7 other bits can be decoded according to a separate cable channel priority vector table 160, which could be stored in ROM 54 of microcontroller 36. The cable channel priority vector table can be set ahead of time for the entire country or at least for an area covered by a particular wide area television guide publication.

1           A television guide that carries the compressed code known as the G-code  
will now print the cable channel information as follows:

                  6:30 pm  
5           [C2] HBO   xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx (4679)  
                  xxxxxx(program description)xxxxxxxxxxxxxx  
                  xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

10           The [C2] in front of HBO reminds the viewer that he needs only to push CABLE  
CHANNEL 2 to select HBO. The (4679) is the G-code indication for this  
particular program.

15           FIG. 8 shows a section of a television guide. The cable channels all have  
an assigned cable channel number 188 in front of the cable channel mnemonic.  
Other than that the cable channel information is arranged the same as the  
broadcast channels with a compressed G-code 212 associated with the channel.

20           For timer preprogramming, the viewer need only enter the number 4679  
according to the unit's G-code entry procedure, e.g., PROG 4679 PROG. The  
G-code decoder unit will decode this G-code into "cable channel 2" and will also  
signal the command controller 36 with a cable channel signal 164, as shown in  
FIGS. 1 and 2, because the extra channel bit will be "1" which distinguishes that  
the G-code is for a cable channel; then, since the association of "cable  
channel 2" with channel 24 has been established earlier in the "setting"  
procedure, the command controller, if it has received a cable channel signal, will  
immediately look up 2 in the cable channel address table 162 to translate it to  
cable channel 24, which will be used as the recording channel at the appropriate  
time. By associating the G-code with the assigned cable channel number rather  
than the local cable channel number, the G-code for that program will be valid  
in the whole local area, which may have many different cable carriers each of  
which may have different local cable channel numbers.

30           To include the cable channel compressed G-code feature, the decoding  
and encoding algorithms are as shown in FIGS. 9 and 10, respectively. The  
encoding should be explained first before the decoding. The primary change in  
FIG. 10 from FIG. 7 is that a cable channel priority vector table 160 has been  
added and is used in look up priority step 180 if a cable channel is being  
encoded. Also if a cable channel is being encoded then the cable channel bit is  
added in the correct bit position in the convert  $C_p D_p T_p L_p$  to binary numbers  
step 182. This could be bit  $C_3$ , as discussed before. The bit hierarchy key could

1        be determined as before to compress the number of bits in the most popular programs; however, it needs to be 23 bits long to accommodate the cable channel bit. The maximum compressed G-code length could still be 7 digits, because  $2^{23} = 8,388,608$ .

5        The decoding is shown in FIG. 9 and is just the reverse of the encoding process. After step 108, test cable channel bit 174 is added and effectively tests the cable channel bit to determine if it is a "1". If so then the command controller 36 is signaled via cable channel signal 164 of FIGS. 1 and 2 that the CDTL 118 that will be sent to it from G-code decoder 38 is for a cable channel.  
10       Then the command controller knows to look up the local cable carrier channel number based on the assigned cable channel number. In step 176 of FIG. 9, the priority vector tables including the cable channel priority vector table 160 are used to look up the CDTL 118 information.

15       An alternate to having the command controller receive a cable channel signal 164 is for the G-code decoder to perform all of the decoding including the conversion from assigned cable channel number to local cable carrier number. This would be the case for the remote controller implementation of FIG. 3. FIG. 11 shows the implementation of the entire decode algorithm if this step is included. All that needs to be added is convert assigned channel to local cable  
20       carrier channel step 166, which performs a look-up in cable channel address table 162, if the cable channel bit indicates that a cable channel is involved. Step 166 effectively replaces step 174 in FIG. 9.

25       Another issue that needs addressing is the number of programs that can be preprogrammed. Since the G-code greatly simplifies the process of entering programs, it is likely that the user will quickly learn and want to enter a large number of programs; however, some existing VCRs can only store up to four (4) programs, while some can store as many as eight. Thus, the user may get easily frustrated by the programming limitations of the VCR.

30       One approach to this problem, is to perform the compressed G-code decoding in the remote controller and provide enough memory there to store a large number of programs, e.g., 20 or 40. The remote controller would have the capability of transferring periodically several of these stored programs at a time to the VCR main unit. To provide this capability, extra memory called stack  
35       memory 76 is required inside the remote unit, as shown in FIG. 12, which other than that is identical to FIG. 4. Stack memory 76 can be implemented with a random access memory, which may in fact reside in the microcontroller itself, such as RAM 62.

1           The stack memory 76 is where new entry, insertion & deletion of timer  
preprogramming information is carried out. It is also where editing takes place.  
The top memory locations of the stack, for example the first 4 locations,  
correspond exactly to the available timer preprogramming memory in the  
5           VCR main unit. Whenever the top of the stack memory is changed, the new  
information will be sent over to the VCR main unit to update it.

          FIG. 13 shows the sequence of events when the user enters a G-code  
program on the keypad of the remote controller. For illustration purposes,  
suppose the VCR main unit can only handle four (4) programs. Suppose also  
10          that the stack memory capacity is 20 timer preprograms. Referring to the  
flowchart in FIG. 13, when the user enters a G-code in step 230, the  
microcontroller 60 first decodes it into the CDTL information in step 234 and  
displays it on the display unit with the additional word "entered" also displayed.  
The microcontroller then enters the decoded program into the stack memory in  
15          step 236.

          If this is the first program entered, it is placed at the top location of the  
stack memory. If there are already programs in the stack memory, the newly  
entered program will first be provisionally placed at the bottom of the stack  
memory. The stack memory will then be sorted into the correct temporal order  
20          in step 240, so that the earliest program in time will appear in the top location  
and the last program in time will be at the bottom. Notice that the nature of the  
temporally sorted stack memory is such that if stack memory location n is  
altered, then all the locations below it will be altered.

          For example, suppose the stack memory has six (6) entries already  
25          temporally ordered, and a new entry is entered whose temporal ordering places  
it in location 3 (1 being the top location). If this entry is placed into location 3,  
information which was in location 3, 4, 5, 6 will be shifted to locations 4, 5, 6,  
and 7. Locations 1 and 2 will remain unchanged.

          The microcontroller 60, after doing the temporal ordering, checks in  
30          step 242 whether the first n entries have changed from before, where for the  
current example n equals 4. In this case, since a new program has been entered  
into location 3, what used to be in location 3 now moves to location 4. Since  
the VCR's main unit program menu of 4 entries should correspond exactly to  
location 1 through 4 of the stack memory, entries 3 and 4 on the VCR main unit  
35          must now be revised. The microcontroller therefore sends out the new entries 3  
& 4 to the main unit, in step 244 of FIG. 13. If the newly entered program, after  
temporal ordering, gets entered into location 5, then entries 1 through 4 have not

1 changed from before and the microcontroller will not send any message to the  
VCR main unit and the microcontroller will just resume monitoring the clock 85  
and the keyboard 88 as per step 246. It is assumed that when the user enters  
the G-code in step 230, the remote controller is pointed at the VCR main unit.  
5 The other steps of FIG. 13 happen so fast that the changes are sent in step 244  
while the remote controller is still being pointed at the VCR main unit.

If the user decides to delete a program in step 232, the deletion is first  
carried out in the stack memory. If the first 4 entries are affected, the  
microcontroller will send the revised information over to the VCR main unit. If  
10 the first 4 entries are not affected, then again the remote controller unit will not  
send anything. The deletion will only change the lower part of the stack (lower  
meaning location 5 to 20). This new information will be sent over to the VCR  
main unit at the appropriate time.

In the meantime, the VCR main unit will be carrying out its timer  
15 programming function, completing its timing preprogramming entries one by one.  
By the time all 4 recording entries have been completed, the stack in the remote  
must send some new entries over to "replenish" the VCR main unit (if the stack  
has more than 4 entries).

The real time clock 85 in the remote controller unit is monitored by the  
20 microcontroller to determine when the programs in the main unit have been used  
up. Referring to the flowchart in FIG. 14, the microcontroller periodically checks  
the clock and the times for the programs at the top of the stack in step 250 (say  
the first 4 entries), which are identical to the VCR's main unit's menu. If on one  
of the periodic checks, it is determined that the recording of the main unit's  
25 menu is complete, then if there are more entries in the stack, which is tested in  
step 252, the display unit will be set to a blinking mode or display a blinking  
message in step 258 to alert the user to send more programs. Next time the  
user picks up the remote unit, the blinking will remind him that the VCR main  
unit's program menu has been completed and it is time to replenish the VCR  
30 main unit with program entries stored in the remote. The user simply picks up  
the remote and points it towards the VCR main unit and presses "ENTER". This  
will "pop" the top of the stack memory in step 260, i.e., pop all the entries in the  
stack up by four locations. The microcontroller will then send the new "top of  
the stack" (i.e., top 4 entries) over to the VCR main unit in step 262. This  
35 process will repeat until the whole stack has been emptied.

Another preferred embodiment of an apparatus for using compressed  
codes for recorder preprogramming is the instant programmer 300 of FIG. 15.

1       The instant programmer 300 has number keys 302, which are numbered 0  
through 9, a CANCEL key 304, a REVIEW key 306, a WEEKLY key 308, a  
ONCE key 310 and a DAILY (M-F) key 312, which are used to program the  
instant programmer 300. A lid normally covers other keys, which are used to  
5       setup the instant programmer 300. When lid 314 is lifted, the following keys are  
revealed: SAVE key 316, ENTER key 318, CLOCK key 320, CH key 322,  
ADD TIME key 324, VCR key 326, CABLE key 328, and TEST key 330. Other  
features of instant programmer 300 shown on FIG. 15 are: liquid crystal display  
350 and red warning light emitting diode 332. The front elevation view FIG. 16  
10       of instant programmer 300 shows front infrared (IR) diode 340 mounted on the  
front side 338. By placing instant programmer 300 in front of the equipment  
to be programmed such as video cassette recorder 370, cable box 372, and  
television 374, as shown in FIG. 19, the front infrared (IR) diode 340 can  
transmit signals to control program recording. An IR transparent cover 336  
15       covers additional IR transmission diodes, which are explained below.

FIG. 18 shows a detail of the liquid crystal display 350. Certain text 354  
is at various times visible on the display and there is an entry area 356. Time  
bars 352 are displayed at the bottom of the display and their function is  
described below.

20       A companion element to the instant programmer 300 is the mounting  
stand 360, shown in FIG. 17, which is designed to hold instant programmer 300  
between left raised side 362 and right raised side 364. The instant programmer  
300 is slid between left raised side 362 and right raised side 364 until coming  
to a stop at front alignment flange 365, which is at the front of mounting stand  
25       360 and connected across left raised side 362 and right raised side 364, as  
shown in FIG. 17A. Together elements 362, 364 and 365 provide alignment for  
instant programmer 300 so that IR transparent cover 336 and the IR diodes 342,  
344, 346 and 348, shown in FIG. 17 are properly aligned for transmission, when  
the instant programmer is used as shown in FIG. 20. The mounting stand 360  
30       has an alignment flange 366, which has the purpose of aligning the back edge  
of mounting stand 360, which is defined as the edge along which alignment  
flange 366 is located, along the front side of a cable box or VCR, or similar unit  
as shown in FIG. 20. When aligned as shown in FIG. 20, the mounting stand  
360 aligns the instant programmer 300 so that the left IR diode 342, down  
35       IR diode 344, two back IR diodes 346 and right IR diode 348, as shown in FIG.  
17, are in position to transmit signals to video cassette recorder 370 and cable  
box 372, as necessary. If the VCR and/or cable box functions are located within

1       the television 374 itself, then the instant programmer 300 could be positioned  
to transmit to the television 374, either in the manner of FIG. 19 or by placing  
the mounting stand on top of the television in the manner of FIG. 20.

5       By using mounting stand 360, the user only need to align the mounting  
stand 360, and the instant programmer 300 once with the equipment to be  
programmed rather than having the user remember to keep the instant  
programmer 300 in the correct location to transmit via front infrared (IR)  
diode 340, as shown in FIG. 19. Current experience with various remote  
10       controllers shows that it is difficult at best to keep a remote controller in a fixed  
location, for example, on a coffee table. The mounting stand 360 solves this  
problem by locating the instant programmer 300 with the equipment to be  
controlled. The left IR diode 342, down IR diode 344, two back IR diodes 346  
and right IR diode 348 are positioned to transmit to the left, downward,  
backward, and to the right. The downward transmitter assumes that mounting  
15       stand 360 will be placed on top of the unit to be programmed. The left and right  
transmission allows units to the left or right to be programmed. The backward  
transmission back IR diodes 346 are provided so that signals can bounce off  
walls and other objects in the room. The front IR diode 340, the left IR diode  
342, the right IR diode 348 and the down IR diode 344 are implemented with  
20       25 degree emitting angle diodes. Two back IR diodes are provided for greater  
energy in that direction and are implemented with 5 degree emitting angle  
diodes, which focus the energy and provide for greater reflection of the IR energy  
off of walls or objects in the room.

25       Most VCR's and cable boxes can be controlled by an infrared remote  
controller; however, different VCR's and cable boxes have different IR codes.  
Although there are literally hundreds of different models of VCR's and cable  
boxes, there are fortunately only tens of sets of IR codes. Each set may have  
a few tens of "words" that represent the different keys required, e.g., "power",  
"record", "channel up", "channel down", "stop", "0", "1", "2" etc. For the  
30       purpose of controlling the VCR and cable box to do recording, only the following  
"words" are required: "0", "1", "2", "3", "4", "5", "6", "7", "8", "9", "power",  
"record", "stop". The IR codes for these words for all the sets are stored in the  
memory of the instant programmer 300, which is located in microcomputer 380  
of FIGS. 21 and 22. During setup of the instant programmer 300, the user  
35       interactively inputs to the instant programmer 300 the type and model of his  
VCR and cable box. The correct set of IR codes will be recalled from memory  
during the actual control process. In the case where the user only has a VCR,

1       the infrared (IR) codes for that particular VCR will be recalled to control the VCR.  
In the case where the user has a VCR and a cable box, the IR codes "power",  
"record", "stop" will be recalled from the set that corresponds to the VCR  
whereas the IR codes for "0" through "9" will be recalled from the set that  
5       corresponds to the cable box. The reason is that in this case, the cable box  
controls the channel switching. Hence the channel switching signals "0" through  
"9" must be sent to the cable box instead of the VCR.

Initially, the user performs a setup sequence. First, the user looks up the  
number corresponding to the model/brand of VCR to be programmed in a table,  
10       which lists the VCR brand name and a two digit code. Then with the VCR tuned  
to Channel 03 or Channel 04, whichever is normally used, the user turns the  
VCR "OFF". Then the user presses the VCR key 326. When the display shows  
VCR, the user presses the two-digit code looked up in the VCR model/brand table  
(for example 01 for RCA). The user points the instant programmer 300 at the  
15       VCR and then presses ENTER key 318. The red warning light emitting diode 332  
will flash while it is sending a test signal to the VCR. If the VCR turned "ON"  
and changed to Channel 09, the user presses the SAVE key 316 and proceeds  
to the set clock step. If the VCR did not turn "ON" or turned "ON" but did not  
change to Channel 09 the user presses ENTER key 318 again and waits until red  
20       warning light emitting diode 332 stops flashing. The instant programmer 300  
sends the next possible VCR code, while the red warning light emitting  
diode 332 is flashing. If the VCR turns "ON" and changed to Channel 09 the  
user presses SAVE key 316, otherwise the user presses ENTER key 318 again  
until the VCR code is found that works for the VCR. The display shows "END"  
25       if all possible VCR codes for that brand are tried. If so, the user presses  
VCR key 326 code 00 and then ENTER key 318 to try all possible codes, for all  
brands, one at a time.

Once the proper VCR code has been found and saved, the next setup step  
is to set the clock on instant programmer 300. First, the user presses the  
30       CLOCK key 320. When the display shows: "YR:", the user presses the year  
(for example 90), then presses ENTER key 318. Then the display shows "MO:",  
and the user presses the month (for example 07 is July), and then presses  
ENTER key 318. This is repeated for "DA:" date (for example 01 for the 1st),  
"Hr:" hour (for example 02 for 2 o'clock), "Mn:" minute (for example 05 for  
35       5 minutes), and "AM/PM:" 1 for AM or 2 for PM. After this sequence, the  
display will show "SAVE" for a few seconds and then the display will show the

1       current time and date that have been entered. It is no longer necessary for the user to set the clock on his/her VCR.

5       Next, if the instant programmer 300 is also to be used as a cable box controller, then the setup steps are as follows. First, the number corresponding to the model/brand of cable box (converter) to be controlled is looked up in a cable box model brand table, that lists cable box brands and corresponding two digit codes. The VCR is tuned to Channel 03 or 04 and turned "OFF". Then the cable box is tuned to Channel 02 or 03, whichever is normal, and left "ON". Then the CABLE key 328 is pressed. When the display shows: "CA B-:" the user enters the two digit code looked up in cable box model brand table, points the instant programmer 300 at the cable box (converter) and presses ENTER key 318. The red warning light emitting diode 332 will flash while it is sending a test signal to the cable box. If the cable box changed to Channel 09: then the user presses SAVE key 316; however, if the cable box did not change to Channel 09 the user presses ENTER key 318 again and waits until red warning light emitting diode 332 stops flashing, while the next possible code is sent. This is repeated until the cable box changes to Channel 09 and when it does the user presses SAVE key 316. If the display shows "END" then the user has tried all possible cable box codes for that brand. If so, the user presses cable code 00 and then ENTER key 318 to try all possible brand's codes, one at a time.

20       For some people (probably because they have cable or satellite), the channels listed in their television guide or calendar are different from the channels on their television or cable. If they are different, the user proceeds as follows. First, the user presses the CH key 322. The display will look like this: "Guide CH TV CH". Then the user presses the channel printed in the television guide or calendar (for example, press 02 for channel 2), and then the user presses the channel number that the printed channel is received on through his/her local cable company. Then the user presses ENTER key 318. This is repeated for each channel listing that is on a different channel than the printed channel. When this procedure is finished the user presses SAVE key 316.

30       Typically the television guide or calendar in the area will have a chart indicating the channel number that has been assigned to each Cable and broadcast channel, for example: HBO, CNN, ABC, CBS, NBC, etc. This chart would correspond, for example, to the left two columns of FIG. 28. For example, suppose the television guide or calendar has assigned channel 14 to HBO but the user's cable company delivers HBO on channel 18. Since the channel numbers are different, the user needs to use the CH key 322. The user

1 will press the CH button (the two blank spaces under the display "Guide CH" will  
flash). The user then presses 14. (now the two blank spaces under the display  
"TV CH" will flash). The user then presses 18 and then ENTER key 318. This  
5 is repeated for each channel that is different. When finished, the user presses  
SAVE key 316.

After the channel settings have been saved, the user may review the  
settings by pressing CH key 322 and then REVIEW key 306. By repeated  
pressing of the REVIEW key 306 each of the set channels will scroll onto the  
display, one at a time.

10 Then the user can test to make sure that the location of the instant  
programmer 300 is a good one. First, the user makes sure that the VCR is  
turned "OFF" but plugged in and makes sure that the cable box (if there is one)  
is left "ON". Then the user can press the TEST key 330. If there is only a VCR,  
then if the VCR turned "ON", changed to channel 09 and started recording, and  
15 then turned "OFF", then the VCR controller is located in a good place.

If there is also a cable box, then if the VCR turned "ON", the cable box  
turned to channel 09 and the VCR started recording, and then the VCR stopped  
and turned "OFF", then the instant programmer 300 is located in a good place.

To operate the instant programmer 300, the VCR should be left OFF and  
20 the cable box ON. The user looks up in the television guide the compressed code  
for the program, which he/she wishes to record. The compressed code 212 is  
listed in the television guide, as shown in FIG. 8. The television guide/calendar  
that would be used with this embodiment would have the same elements as  
shown on FIG. 8 except that element 188 of FIG. 8 is not required. The  
25 compressed code 212 for the program selected by the user is entered into the  
instant programmer 300 by using the number keys 302 and then the user selects  
how often to record the program. The user presses the ONCE key 310 to record  
the program once at the scheduled time, or the user presses the WEEKLY  
key 308 to record the program every week at the same scheduled time until  
30 cancelled or the user presses the DAILY (M-F) key 312 to record the program  
each day Monday through Friday at the same scheduled time until cancelled.  
This is most useful for programs such as soapbox operas that air daily, but not  
on the weekend. To confirm the entry, the instant programmer 300 will  
immediately decode the compressed code and display the date, channel and start  
35 time of the program entered by the user. The length of the entered program is  
also displayed by time bars 352 that run across the bottom of the display. Each  
bar represents one hour (or less) of program.

1           Then the user just needs to leave the instant programmer 300 near the  
VCR and cable box so that commands can be transmitted, and at the right time,  
the instant programmer 300 will turn "ON" the VCR, change to the correct  
channel and record the program and then turn the VCR "OFF". The user must  
5           just make sure to insert a blank tape.

          The REVIEW key 306 allows the user to step through the entered  
programs. These are displayed in chronological order, by date and time. Each  
time the REVIEW key 306 is pressed, the next program is displayed, until "END"  
is displayed, when all the entered programs have been displayed. If the REVIEW  
10          key 306 is pressed again the display will return to the current date and time.

          If the user wishes to cancel a program, then the user presses REVIEW key  
306 until the program to cancel is displayed, then the user presses CANCEL key  
304. The display will say "CANCELLED". Also, any time the user presses a  
wrong number, pressing the CANCEL key 304 will allow the user to start over.

15          Certain television programs, such as live sports, may run over the  
scheduled time slot. To ensure that the entire program is recorded, the user may  
press the ADD TIME key 324 to increase the recording length, even while the  
program is being recorded. The user presses the REVIEW key 306 to display the  
program, then presses ADD TIME key 324. Each time ADD TIME key 324 is  
20          pressed, 15 minutes is added to the recording length.

          When the current time and date is displayed, the amount of blank tape  
needed for the next 24 hours is also displayed by the time bars 352 that run  
across the bottom of the display. Each bar represents one hour (or less) of tape.  
The user should check this before leaving the VCR unattended to ensure that  
25          there is enough blank tape.

          Each time a program code is entered, the instant programmer 300  
automatically checks through all the entries to ensure that there is no overlap in  
time between the program entries. If the user attempts to enter a program that  
overlaps in time with a program previously entered, then the message "CLASH"  
30          appears. Then, as summarized by step 432 of FIG. 23, the user has the  
following options: 1) if the user wishes to leave the program previously entered  
and forget about the new one, the user does nothing and after a short time  
delay, the display will return to show the current time and date; 2) if the user  
wishes the program which starts first to be recorded to its end, and then to  
35          record the remainder of the second program, then the user presses ONCE key  
310, DAILY (M-F) key 312, or WEEKLY key 308 again (whichever one the user  
pushed to enter the code). If the programs have the same starting time, then the

1 program most recently entered will be recorded first. If on being notified of the  
"CLASH", the user decides the new program is more important than the  
previously entered program, then the user can cancel the previously entered  
program and then re-enter the new one.

5 In some locations, such as in some parts of Colorado, the cable system  
airs some channels three (3) hours later/earlier than the times listed in the local  
television guide. This is due to time differences depending on whether the  
channel is received on a east or west satellite feed. For the user to record the  
10 program 3 hours later than the time listed in the television guide the procedure  
is as follows. First the user enters the code for the program and then presses  
SAVE key 316 (for +) and then presses ONCE key 310, DAILY (M-F) key 312,  
or WEEKLY key 308, as desired. For the user to record the program 3 hours  
earlier than the time listed in the television guide the procedure is as follows.  
15 First the user enters the code for the program and then presses ENTER key 318  
(for -) and then presses ONCE key 310, DAILY (M-F) key 312, or WEEKLY  
key 308, as desired. The instant programmer 300 will display the time that the  
program will be recorded, not the time shown in the television guide.

There are certain display messages to make the instant programmer 300  
more user friendly. The display "LO BATT" indicates that the batteries need  
20 replacement. "Err: ENTRY" indicates an invalid entry during setup. "Err: CODE"  
indicates that the program code number entered is not a valid number. If this is  
displayed the user should check the television guide and reenter the number.  
"Err: DATE" indicates the user may have: tried to select a daily recording  
(Monday to Friday) for a Saturday or Sunday program; tried to select weekly or  
25 daily recording for a show more than 7 days ahead, because the instant  
programmer 300 only allows the weekly or daily recording option to be used for  
the current weeks' programs ( $\pm 7$  days); or tried to enter a program that has  
already ended. "FULL" indicates that the stack storage of the programs to be  
recorded, which is implemented in random access memory (RAM) inside the  
30 instant programmer 300 has been filled. The user could then cancel one or more  
programs before entering new programs. "EMPTY" indicates there are no  
programs entered to be recorded. The number of programs to be recorded that  
can be stored in the instant programmer 300 varies depending on the density of  
RAM available and can vary from 10 to more.

35 FIG. 21 is a schematic of the circuitry needed to implement the instant  
programmer 300. The circuitry consists of microcomputer 380, oscillator 382,  
liquid crystal display 384, key pad 386, five way IR transmitters 390 and red

1 warning light emitting diode 332. The microcomputer 380 consists of a CPU,  
ROM, RAM, I/O ports, timers, counters and clock. The ROM is used for program  
storage and the RAM is used among other purposes for stack storage of the  
5 programs to be recorded. The liquid crystal display 384 is display 350 of  
FIGS. 15 and 18. The key pad 386 implements all the previously discussed  
keys. The five way IR transmitters 390 consists of front infrared (IR) diode 340,  
left IR diode 342, down IR diode 344, two back IR diodes 346 and right  
10 IR diode 348. FIG. 22 shows the detailed schematic of the instant programmer  
300 circuitry and previously identified elements are identified by the same  
numbers. The microcomputer can be implemented with a NEC  $\mu$ PD7530x part,  
which can interface directly with the display, the keypad, the light emitting  
diodes and the oscillator. The 25 degree IR diodes can be implemented with  
NEC 313AC parts and the 5 degree IR diodes can be implement with  
15 Litton 2871C IR diodes.

The flowcharts for the program that is stored in the read only memory  
(ROM) of the microcomputer 380 that executes program entry, review and  
program cancellation, and record execution are illustrated in FIGS. 23, 24, and  
25, respectively. The FIG. 23 for program entry, which process was described  
above, consists of the following steps: display current date, time and time bars  
20 step 402, which is the quiescent state of instant programmer 300; scan  
keyboard to determine if numeric decimal compressed code entered step 404;  
display code as it is entered step 406; user checks if correct code entered step  
408 and user presses CANCEL key 304 step 428; user advances or retards start  
time by three hours by pressing SAVE key 316 or ENTER key 318 step 410; user  
25 presses ONCE key 310, WEEKLY key 308 or DAILY key 312 key step 412;  
microcomputer decodes compressed code into CDTL step 414; test if conflict  
with stored programs step 416, if so, display "CLASH" message step 420, user  
presses ONCE key 310, WEEKLY key 308 or DAILY key 312 step 422, then  
accommodate conflicting entries step 432, as described above in the discussion  
30 of the "CLASH" options, and entry not saved step 424; set display as date,  
channel, start time and duration (time bars) for ONCE, or DA, channel, start time  
and duration for DAILY, or day of week, channel, start time and duration for  
WEEKLY step 418; user presses ADD TIME key 324, which adds 15 minutes to  
record time step 426; user checks display step 430; enter program on stack in  
35 chronological order step 434 wherein the stack is a portion of the RAM of  
microcontroller 380; and calculate length of tape required and update time bars  
step 436.

1           The FIG. 24 flowchart for review and cancellation, which process was  
described above, consists of the following steps: display current date, time and  
time bars step 402; REVIEW key 306 pressed step 442; test if stack empty  
step 444, display "EMPTY" step 446, and return to current date and time display  
5           step 448; display top stack entry step 450; user presses ADD TIME key 324  
step 452 and update time bars step 460; user presses REVIEW key 306  
step 454 and scroll stack up one entry step 462; user presses CANCEL key 304  
step 456 and display "CANCELLED" and cancel program step 464; and user does  
nothing step 458 and wait 30 seconds step 466, wherein the 30 second timeout  
10          can be implemented in the timers of microcomputer 380.

          The FIG. 25 flowchart for record execution, which is the process of  
automatically recording a program and which was described above, consists of  
the following steps: compare start time of top program in stack memory with  
current time step 472; test if three minutes before start time of program  
15          step 474; start red warning LED 332 blinking for 30 seconds step 476; display  
channel, start time and blinking "START" message step 478, is correct start time  
reached step 480 and send power ON signal to VCR and display "REC" message  
step 482; test if a cable box is input to VCR step 484, send channel switching  
signals to VCR step 486 and send channel switching signals to cable box  
20          step 488; send record signals to VCR step 490; compare stop time with current  
time step 492, test if stop time reached step 494 and display "END"  
message step 496; send stop signals to VCR step 498; send power OFF signal  
to VCR step 500; and pop program stack step 502.

          FIG. 26 is a flowchart of the method for encoding channel, date, time and  
25          length (CDTL) into decimal compressed code 510. This process is done  
"off-line" and can be implemented on a general purpose computer and is done  
to obtain the compressed codes 212 that are included in the program guide or  
calendar of FIG. 8. The first step in the encoding method is the enter channel,  
date, time and length (CDTL) step 512 wherein for a particular program the  
30          channel, date, start time and length CDTL 514 of the program are entered. The  
next step is the look-up assigned channel number step 516, which substitutes  
an assigned channel number 522 for each channel 518. Often, for example for  
network broadcast channels, such as channel 2, the assigned channel number  
is the same; however, for a cable channel such as HBO a channel number is  
35          assigned and is looked up in a cable assigned channel table 520, which would  
essentially be the same as the first two columns of the table of FIG. 28. Next,  
the look-up priority of channel, date and time/length in priority vector tables

1 step 524 performs a look-up in priority vector channel (C) table 526, priority  
vector date (D) table 528 and priority vector time/length (TL) table 530 using the  
indices of channel, date and time/length, respectively, to produce the vector  
5  $C_p$ ,  $D_p$ ,  $TL_p$  532. The use of a combined time/length (TL) table to set priorities  
recognizes that there is a direct relationship between these combinations and the  
popularity of a program. For example, at 6:30 PM, a short program is more likely  
to be popular than a 2 hour program, because it may be the dinner hour.

The channel priority table is ordered so that the most frequently used  
channels have a low priority number. An example of the data that is in the  
10 priority vector C table 526 follows.

channel	4	7	2	3	5	6	11	13	...
priority	0	1	2	3	4	5	6	7	...

15 Generally the dates of a month all have an equal priority or equal usage,  
so the low number days in a month and the low number priorities would  
correspond in the priority vector D table 528 as in the following example.

date	1	2	3	4	5	6	7	8	...
20 priority	0	1	2	3	4	5	6	7	...

The priority of the start times and length of the programs could be  
arranged in a matrix that would assign a priority to each combination of start  
times and program lengths so that more popular combinations of start time and  
25 length would have a low priority number and less popular combinations would  
have a high priority number. For example, a partial priority vector T/L table 530  
might appear as follows.

Priority TL Table					
30 TIME	6:30pm	7:00pm	7:30pm	8:00pm	...
Length (hrs)					
0.5	8	4	7	10	
1.0	12	15	13	18	
1.5	20	19	17	30	

35

Suppose the channel, date, time and length (CDTL) 514 data is channel 5,  
February 10, 1990, 7:00PM and 1.5 hours in length, then the  $C_p, D_p, TL_p$  data 532

1 for the above example would be 4 9 19. The next step is the convert  $C_p$ ,  $D_p$ ,  $TL_p$   
to binary numbers and concatenate them into one binary number step 534,  
resulting in the data word  $...TL_2TL_1...C_2C_1...D_2D_1$  536. For the example given  
above, converting the  $...TL_2TL_1...C_2C_1...D_2D_1$  536 word to binary would yield the  
5 three binary numbers:  $...0010011$ ,  $...0100$ ,  $...01001$ . The number of binary bits  
to use in each conversion is determined by the number of combinations involved.  
This could vary depending on the implementation; however one preferred  
embodiment would use eight bits for  $C_p$ , denoted as  $C_8 C_7 C_6 C_5 C_4 C_3 C_2 C_1$ ,  
which would provide for 256 channels, five bits for  $D_p$ , which can be denoted as  
10  $D_5 D_4 D_3 D_2 D_1$ , would provide for 31 days in a month, and fourteen bits for  $TL_p$ ,  
denoted as  $TL_{14}... TL_3 TL_2 TL_1$ , which would provide for start times spaced every  
5 minutes over 24 hours and program lengths in increments of 5 minute lengths  
for programs up to 3 hours in length and program length in increments of  
15 15 minute lengths for programs from 3 to 8 hours in length. This requires about  
 $288 \times (36 + 20) = 16,128$  combinations, which are provided by the  
 $2^{14} = 16,384$  binary combinations. Altogether there are  $8 + 5 + 14 = 27$  bits  
of information  $TL_{14}...TL_2TL_1C_8...C_2C_1D_5...D_2D_1$ . For the above example padding  
each number with zeros and then concatenating them would yield the 27 bit  
binary number: 000000000100110000010001001.

20 The next step is to use bit hierarchy key 540, which can be stored in read  
only memory 64 to perform the reorder bits of binary number according to bit  
hierarchy key step 538. As described previously, a bit hierarchy key 540 can be  
any ordering of the  $...TL_2TL_1...C_2C_1...D_2D_1$  536 bits and in general will be  
selected so that programs most likely to be the subject of timer preprogramming  
25 would have a low value compressed code 212, which would minimize  
keystrokes. The ordering of the bit hierarchy key can be determined by the  
differential probabilities of the various bit combinations as previously discussed.  
The details of deriving a bit hierarchy key 540 were described relative to bit  
hierarchy key 120 and the same method can be used for bit hierarchy key 540.  
30 For example, the bit hierarchy key might be:

$TL_8$	$C_3$	...	$TL_{10}$	$C_2$	$TL_1$	$C_1$	$L_1$	$D_5$	$D_4$	$D_3$	$D_2$	$D_1$
27	26	...	10	9	8	7	6	5	4	3	2	1

35 The next step is the combine groups of bits and convert each group into  
decimal numbers and concatenate into one decimal number step 542. For  
example, after reordering according to the bit hierarchy key, the code may be

1        000000001010010000010001001, which could be grouped as  
       00000000101001000,0010001001. If these groups of binary bits are  
       converted to decimal as 328,137 and concatenated into one decimal number,  
       then the resulting decimal number is 328137. The last encoding step is the  
 5        permute decimal number step 546, which permutes the decimal number  
       according to permutation function 544 that is dependent on the date 548 and in  
       particular the month and year and provides a security feature for the codes.  
       After the permute decimal number step 546, the decimal compressed code  
        $G_8...G_2G_1$  550 may, for example, be 238731. These encoded codes are then  
 10       included in a program guide or calendar as in the compressed code indication 212  
       of FIG. 8.

      FIG. 27 is a flowchart of the method for decoding a decimal compressed  
       code into channel, date, time and length 560, which is step 414 of FIG. 23.  
       Once the decimal compressed code  $G_8...G_2G_1$  564 is entered in step 562, it is  
 15       necessary to invert the permutation function of steps 544 and 546 of FIG. 26.  
       The first step is the extract day code step 566, which extracts the day code for  
       the program in the decimal compressed code and passes the day code to step  
       568, which also receives the current day 574 from the clock 576, which is  
       implemented by microcomputer 380 in FIGS. 21 and 22. The clock 576 also  
 20       sends the current month and year to the permutation function 570, which is  
       dependent on the month and year. Then step 568 performs the function: if day  
       code is same or greater than current day from clock, then use permutation  
       function for month/year on clock, otherwise use permutation function for next  
       month after the month on the clock and use next year if the month on the clock  
 25       is December. In other words, since there is provision for preprogramming  
       recording for one month or 31 days ahead, if the day for the program is equal to  
       or greater than the current day of the month, then it refers to a day in the  
       present month; otherwise, if the day for the program is less than the current day  
       of the month, it must refer to a program in the next month. The extract day  
 30       code step 566, which must be performed before the invert permutation of  
       decimal compressed code step 580, is accomplished by a prior knowledge of  
       how the permute decimal number step 546 of FIG. 26 is performed relative to  
       the day code information.

      The selected permutation method 578 is used in the invert permutation  
 35       of decimal compressed code step 580. For the example given above, the output  
       of step 580 would be: 328137. The next step is the convert groups of decimal  
       numbers into groups of binary numbers and concatenate binary groups into one

1        binary number step 584, which is the inverse of step 542 of FIG. 26 and for the  
       above example would result in the binary code:  
       000000001010010000010001001. Then the bit hierarchy key 588 is used in  
       the reorder bits of binary number according to bit hierarchy key step 586, which  
 5        inverts step 538 of FIG. 26 to obtain 000000000100110000010001001 for the  
       above example, which is ... $TL_2 TL_1 \dots C_2 C_1 \dots D_2 D_1$  582 corresponding to 536 of  
       FIG. 26. The next step is to group bits to form three binary numbers  $TL_b$ ,  $C_b$ ,  $D_b$   
       and convert to decimal numbers step 590 resulting in  $C_p$ ,  $D_p$ ,  $TL_p$  592, which for  
       the example above would be: 4, 9, 19, and which are priority vectors for  
 10        channel, day and time/length, which in turn are used to look up channel, day,  
       time and length 604 in priority vector channel (C) table 598, priority vector  
       date (D) table 600, and priority vector time/length (TL) table 602, respectively.

      The look-up local channel number step 606 looks up the local channel 612  
       given the assigned channel number 608, in the assigned/local channel table 610,  
 15        which is setup by the user via the CH key 322, as explained above. An example  
       of the assigned/local channel table 610 is the right two columns of the  
       assigned/local channel table 620 of FIG. 28. The correspondence between the  
       assigned channel numbers, such as 624 and 628, and the local channel numbers,  
       such as 626 and 630 is established during setup by the user. For the example,  
 20        FIG. 28 shows an exact correspondence between the assigned channel number 5  
       and the local channel number 5. The last step is the append month and year to  
       day to form date step 614. The correct month and year are obtained from  
       step 568 and are again dependent on whether the day code is equal to or greater  
       than the day from the clock or less than the day from the clock. If the day code  
 25        is equal to or greater than the day from the clock, the month and year as shown  
       on the clock are used, otherwise the next month is used and the next year is  
       used if the clock month is December. The result is the channel, date, time and  
       length (CDTL) 618, which for the above example would be channel 5,  
       February 10, 1990, 7:00PM and 1.5 hours in length.

30        Another preferred embodiment is to embed the decoding means into a  
       television receiver with G-code decoder 950, as shown in FIG. 29, which is a  
       block diagram of a system including a television receiver having a G-code  
       decoder. The user would use the television remote controller 956 or controls on  
       the television receiver to enter the code that signifies the program to be  
 35        recorded. The same television remote and controls on the television would also  
       be used to perform normal television control functions, such as channel  
       selection. When a G-code is entered, the television remote would send the

1 G-code to the television with G-code decoder 950 via infrared transmitter 958.  
An infrared receiver 960 on the television receiver 950 would receive the  
transmission and send the code to the G-code decoder 954, which would decode  
the code into CDTL and use this information along with a clock, which would  
5 also be embedded in the television receiver 950, to send the proper commands  
to the VCR 964 and cable box 966 at the appropriate time so that the selected  
program will be recorded at the proper time. The transmission from the  
television 950 would be via infrared transmitters 962, which can be placed at  
strategic points on the television cabinet, such as at the corners. The  
10 transmission is then received by the VCR 964 via infrared receiver 968 and the  
cable box 966 via infrared receiver 969.

FIG. 30 is a schematic of a television receiver having a G-code decoder.  
The television receiver with G-code decoder 950 would receive signals from the  
television remote controller 956 via infrared receiver 960, which would send the  
15 signals to either command controller 974 or directly to G-code decoder 954. The  
command controller 974 may be present in the television receiver to control  
other items in the television, including "on screen" functions such as displaying  
the channel number when the channel is changed. The G-code decoder 954  
would decode a sent G-code and using the date and time from clock 976 would  
20 send the proper commands to the VCR 964 and cable box 966 via infrared  
transmitters 962. The G-codes and other commands could also be sent to the  
command controller via manual control 975. When the G-code is decoded, then  
the G-code and the decoded CDTL information could be displayed "on screen"  
as shown in on screen display 978 on television display/monitor 952. The "on  
25 screen" display is not necessary and any format is optional.

FIG. 31 is a schematic showing apparatus for a G-code decoder in a  
television receiver having G-code decoding. The circuitry is very similar to that  
described in FIGS. 21 and 22; however, there are interfaces to an infrared  
receiver 960 and command controller 974 rather than LCD 384 and Key Pad  
30 386. The key elements are microcontroller 980 and oscillator 982. The  
interface to command controller 974 is one preferred embodiment; another  
embodiment could have direct interfaces between the manual control 975, the  
infrared receiver 960, the television display/monitor 952 and the G-code decoder  
954 without going through the intermediary command controller 974. The  
35 television circuitry would include the capability of storing or learning the infrared  
code protocols for the VCR and the cable box. The warning light emitting  
diode 984 would be mounted on the cabinet of the television to warn that

1 recording was about to begin in order to alert the user to have the VCR ready with tape to record.

With the "on screen" display on television display/monitor 952, the operation of the television receiver with G-code decoder 950 can be essentially identical to that described in FIGS. 23, 24 and 25 for program entry, program review and program cancellation, and execution of recorder preprogramming using compressed codes, respectively. Every that was displayed on LCD 384 would instead be displayed on the television monitor 952. The only difference would be that "on screen" would only perform step 402 (display current date, time and time bars) when the user put television remote controller 956 into a mode for G-code entry and transmission, program review or program cancellation. The method of encoding program channel, date, time and length information into decimal compressed codes of FIG. 26, the method of decoding decimal compressed codes into program channel, date, time and length information of FIG. 27, and the method of assigning channel numbers to local channel numbers as illustrated in FIG. 28 would stay the same.

Another preferred embodiment of the invention is to embed the decoding means into various equipments associated with television, such as a video cassette recorder, cable box or satellite receiver. In any system the decoding means would only have to be present in one of the equipments, such as the cable box, which would then at the appropriate time distribute the proper commands to the other equipments such as a VCR and a satellite receiver to record the desired program.

FIG. 32 is a block diagram of a system including a television having a G-code decoder 950, a VCR 964, a cable box 966 and a satellite receiver 986. This system would work identically to the system shown in FIG. 29, except that a satellite receiver is included, which could receive commands via infrared receiver 988 from infrared transmitters 962 mounted on television receiver with G-code decoder 950. The commands received by the satellite receiver could include on/off commands and channel select commands. The satellite receiver 986 could feed a television signal to VCR 964, which would record the program and/or relay it to television display/monitor 952.

FIG. 33 is a block diagram of a system including a VCR having a G-code decoder 991, a television 952, a cable box 966 and a satellite receiver 986. The user would use the television remote controller 956 or controls on the VCR 991 to enter the code that signifies the program to be recorded. When a G-code is entered, the television remote would send the G-code to VCR 991 with G-code

1 decoder 992 via infrared transmitter 958. An infrared receiver 990 on the  
VCR 991 would receive the transmission and send the code to the G-code  
decoder 992, which would decode the code into CDTL and use this information  
5 along with a clock, which would also be embedded in the VCR 991, to send the  
proper commands to the cable box 966 and the satellite receiver 986 at the  
appropriate time so that the selected program will be recorded at the proper time.  
The transmission from the VCR 991 would be via infrared transmitters 994,  
which can be placed at strategic points on the VCR. The transmission is then  
10 received by the cable box 966 via infrared receiver 969 and the satellite receiver  
986 via infrared receiver 988.

Another preferred embodiment of the transmission method and apparatus  
between equipments is shown in FIG. 36, which is a perspective view showing  
a cable box 372 placed on top of a VCR 370 having an infrared transmitter 1008  
behind the front panel 1009 which communicates to the cable box infrared  
15 receiver 1010 via reflection from surrounding reflecting surfaces such as walls.

Another preferred embodiment of the transmission method and apparatus  
between equipments is shown in FIG. 37, which is a perspective view showing  
a cable box 372 placed on top of a VCR 370 having an infrared transmitter 1014  
inside a infrared dome 1012 on the top of the VCR which communicates to the  
20 cable box infrared receiver 1010 via direct communication or reflection  
depending on placement of the infrared receiver 1010 relative to infrared  
dome 1012.

Another preferred embodiment of the transmission method and apparatus  
between equipments is shown in FIG. 38, which is a perspective view of a  
25 VCR 370 having an infrared transmitter 1022 inside a mouse 1020 coupled via  
a cable 1018, which is plugged via plug 1017 into receptacle 1016 on the VCR.  
The mouse 1020 is placed near the cable box infrared receiver 1010. This  
embodiment is most useful when the cable box is separated from the VCR by  
walls of a cabinet, for example, that would prevent either direct or reflective  
30 infrared transmission.

Another preferred embodiment of the transmission method and apparatus  
between equipments is shown in FIG. 39, which is a perspective view of a  
VCR 370 having an infrared transmitter 1026 inside a stick on miniature  
mouse 1024 coupled via a cable 1018, which is plugged via plug 1017 into  
35 receptacle 1016 on the VCR. The stick on miniature mouse 1024 is stuck onto  
the cable box very near the infrared receiver 1010. This embodiment is also

1 most useful when the cable box is separated from the VCR by walls of a cabinet,  
for example, that would prevent either direct or reflective infrared transmission.

The transmission methods and apparatus of FIGS. 36, 37, 38 and 39  
could also be used with the system of FIG. 32 to transmit information from  
5 television receiver with G-code decoder 950 to VCR 964, cable box 966 and  
satellite receiver 986.

FIG. 34 is a block diagram of a system including a cable box having a  
G-code decoder 997, a television 952, a VCR 964, and a satellite receiver 986.  
The user would use the television remote controller 956 or controls on the cable  
10 box 997 to enter the code that signifies the program to be recorded. When a  
G-code is entered, the television remote would send the G-code to cable box 997  
with G-code decoder 998 via infrared transmitter 958. An infrared receiver 996  
on the cable box 997 would receive the transmission and send the code to the  
G-code decoder 998, which would decode the code into CDTL and use this  
15 information along with a clock, which would also be embedded in the cable  
box 997, to send the proper commands to the VCR 964 and the satellite receiver  
986 at the appropriate time so that the selected program will be recorded at the  
proper time. The transmission from the cable box 997 would be via infrared  
transmitters 1000, which can be placed at strategic points on the cable box.  
20 The transmission is then received by the VCR 964 via infrared receiver 968 and  
the satellite receiver 986 via infrared receiver 988. The transmission methods  
and apparatus of FIGS. 36, 37, 38 and 39 could also be used with the system  
of FIG. 34 to transmit information from cable box 997 to VCR 964 and satellite  
receiver 986.

25 FIG. 35 is a block diagram of a system including a satellite receiver 1005  
having a G-code decoder, a television 952, a VCR 964, and a cable box 966.  
The user would use the television remote controller 956 or controls on the  
satellite receiver 1005 to enter the code that signifies the program to be  
recorded. When a G-code is entered, the television remote would send the  
30 G-code to satellite receiver 1005 with G-code decoder 1004 via infrared  
transmitter 958. An infrared receiver 1002 on the satellite receiver 1005 would  
receive the transmission and send the code to the G-code decoder 1004, which  
would decode the code into CDTL and use this information along with a clock,  
which would also be embedded in the satellite receiver 1005, to send the proper  
35 commands to the VCR 964 and the cable box 966 at the appropriate time so  
that the selected program will be recorded at the proper time. The transmission  
from the satellite receiver 1005 would be via infrared transmitters 1006, which

1 can be placed at strategic points on the satellite receiver. The transmission is  
then received by the VCR 964 via infrared receiver 968 and the cable box 966  
via infrared receiver 969. The transmission methods and apparatus of FIGS. 36,  
37, 38 and 39 could also be used with the system of FIG. 35 to transmit  
5 information from satellite receiver 1005 to VCR 964 and cable box 966.

Another preferred embodiment of an apparatus for using compressed  
codes for a recorder programming is the custom programmer 1100 of FIGS. 40  
and 41. The custom programmer 1100 is similar to instant programmer 300 and  
has number keys 1102, which are numbered 0-9, a CANCEL key 1104, a  
10 REVIEW key 1106, a WEEKLY key 1108, a ONCE key 1110 and a DAILY (M-F)  
key 1112, which correspond directly to keys 302-312 of instant programmer  
300, and which are used to program the custom programmer 1100. Like the  
instant programmer 300, a lid normally covers other keys, which are used to  
setup the instant custom programmer 1100. When lid 1114 is lifted, the  
15 following keys are revealed, but not shown in the drawings: SAVE key, ENTER  
key, CLOCK key, CH key, ADD TIME key, VCR key, CABLE key, and TEST key.  
These keys of the custom programmer 1100 correspond to and operate  
substantially the same as keys 316-330 of instant programmer 300,  
respectively. Also included in the custom programmer 1100 shown in FIG. 40  
20 are: liquid crystal display 1134, red warning light emitting diode 1132 and  
IR diodes 1134, which correspond to liquid crystal display 350, red warning light  
emitting diode 332 and IR diodes 342-348 as shown in FIG. 15.

As discussed above, when using the instant programmer 300, the  
consumer initially performs a setup sequence, consisting of selecting a protocol  
25 for the model/brand of VCR, setting the current real time, selecting a protocol for  
the model/brand of cable box, and entering a series of channel number  
assignments. Although the instant programmer 300 makes recording of  
television programs extremely simple, the initial setup sequence for the instant  
programmer 300 is more complex and deters the use of the instant programmer  
30 by some consumers. Custom programmer 1100 includes a microphone  
opening 1140 through which at least one microphone inside the custom  
programmer 1100 can receive electronically coded audio signals that contain the  
information necessary for the custom programmer's initial setup and commands  
to store this information into the custom programmer 1100.

35 In order to receive these audio signals, a user may call a special phone  
number which could be a toll-free 800 number, a pay-per-minute 900 number,  
or a standard telephone number with standard toll charges applying. The

1 consumer can speak to an operator who orally inquires from the consumer the  
information regarding the consumer's VCR model and brand, zip code, model and  
brand of cable box and the newspaper or other publication which the consumer  
will use to obtain the compressed codes. This is all the information needed to  
5 perform the initial setup for the custom programmer 1100. From the zip code  
information, the operator can determine to which cable system the consumer is  
connected and can combine this data with the knowledge of which publication  
the consumer will use to select the correct local channel mapping table for the  
consumer.

10 The operator then directs the consumer to press a designated  
programming key which is, in the case of the preferred embodiment, the CH key  
located under lid 1114. When the CH key is pressed, the display 1134 with  
display the message "PHONE1 KEY2". Pressing the "2" numeric key places the  
custom programmer into the manual local channel table programming mode that  
15 is implemented by instant programmer 300 when CH key 322 is pressed.  
Pressing the "1" numeric key initiates the remote programming mode. The  
custom programmer 1100 is then ready to receive an audio signal and  
display 1134 displays the message "WAIT".

20 The operator will then direct the consumer to place the earpiece 1142 of  
the telephone receiver 1144 over the microphone opening 1140 of the custom  
programmer 1100 as generally shown in FIG. 42. The earpiece need not be  
placed directly against the custom programmer 1100, but may be held more than  
an inch away from the microphone opening with generally satisfactory results.  
After a pause sufficient to allow the consumer to place the telephone receiver in  
25 the proper position, the operator will initiate the downloading of the initial setup  
data and initial setup programming commands transmitted over the telephone  
line 1146 using audio signals to the consumer's custom programmer 1100.

If the initial setup data is successfully transferred to the custom  
programmer 1100, the display 1134 of the custom programmer 1100 will display  
30 the message "DONE". If the reception of the initial setup data is not successful  
within a predetermined time limit, red warning light emitting diode 1132 will blink  
to inform the consumer to adjust the position of the telephone earpiece before  
another down load of the information is attempted. After a waiting period  
allowing this adjustment, the initial setup data and commands are re-transmitted  
35 over the telephone line. If after a predetermined number of attempts to  
download the initial setup information are unsuccessful, the liquid crystal  
display 1134 displays the message "FAIL" and the operator is again connected

1 to the consumer allowing the operator to speak to the consumer to provide additional assistance in the positioning of the telephone earpiece.

Alternatively, a live operator could be provided by the local cable company and the initial setup information downloaded to the custom programmer 1100 by  
5 telephone line, through the existing cable of the cable system, or any other transmission means. If local cable companies supply the live operators, the only information they would need to gather from the consumer would be the VCR brand and model and the publication containing compressed codes that the consumer plans on using, because the local cable company would know the  
10 model and brand of cable box installed at the consumer's location and the necessary data regarding the local channel designations for that cable system.

FIGS. 43 and 44 are schematics of the circuitry needed to implement alternative embodiments of the custom programmer 1100. The circuit consists of microcomputer 1150, oscillator 1152, liquid crystal display 1154,  
15 keypad 1156, five way IR transmitters 1158 and red warning light emitting diode 1160. These components directly correspond to microcomputer 380, oscillator 382, liquid crystal display 384, keypad 386, five way IR transmitters 388 and red warning light emitting diode 332, respectively of instant programmer 300 and perform in the same manner. In both FIGS. 43 and 44,  
20 earpiece 1142 generates serial audio signals which are received by microphone 1162.

As shown in FIG. 43 the audio signals received by microphone 1162 are passed through amplifier 1164 and forwarded through a DTMF decoder circuit and into a serial port of microcomputer 1150. In the alternative circuit shown  
25 in FIG. 44, the audio signals received by microphone 1162 are passed through amplifier 1166, through a high pass filter 1166 with a cutoff at approximately 1-5 kHz, and through a second amplifier 1170 to a serial port of microcomputer 1150.

Alternatively, a dual microphone system (not shown) may be employed  
30 to increase reliability, especially when the custom programmer 1100 is to be programmed in an environment with a high level of background noise that could interfere with the transmission of data through the single microphone acoustic means. In this system, one microphone would be placed near the telephone earpiece and the second microphone would be place some distance away from  
35 the earpiece in order to pick up background noise. A audio signal cancellation circuit is then used to effectively "subtract" the background noise picked up by the second microphone from the audio data signals combined with the

1 background noise that is picked up from the first microphone resulting in solely clean audio data signals.

Another preferred embodiment includes a separate initial setup programmer 1200 as shown in FIGS. 45. The initial setup programmer 1200 serves the same basic function as the telephonic audio signal programming capability of custom programmer 1100, namely allowing the total setup of the instant programmer 300 or custom programmer 1100 with a minimum of effort on the part of the consumer. Normally, initial setup programmers 1200 would be maintained by sellers of either the instant programmer 300 or the custom programmer 1100. The initial setup programmer could be programmed with the local channel tables for the cable systems and the television calendars that publish G-codes in the vicinity of the seller. When a customer purchases an instant programmer 300 or custom programmer 1100, the seller can inquire where the customer lives and which television calendar the customer uses and use the initial setup programmer 1200 to download the appropriate local channel table for that customer. Further, the initial setup programmer 1200 can also set the clock, VCR brand and model, and cable box brand and model for the customer's instant programmer 300 or custom programmer 1100.

The initial setup programmer 1200 includes a keyboard 1202, a display 1204, an enclosure 1206, and a lid 1208, with hinges 1209 at the top that allow the lid to open to reveal a depression 1210 for holding instant programmers 300 and custom programmers 1100 and two electrical contact pins 1212 as shown in FIG 46. The initial setup programmer 1200 includes a modular phone jack 1230 and a serial port 1232 as shown in FIG. 47 for transferring data to and from computers, either directly or over telephone lines.

FIG. 48 shows two access holes 1213 in the bottom of the instant programmer 300 that allow access to two contact points on the to the circuit board (not shown) inside the instant programmer 300. FIG. 49 shows the initial setup programmer 1200 with an instant programmer 300 fit into the depression 1210 with the two contact pins 1212 extending upwards through the access holes 1213 in the bottom of the instant programmer 300. FIG. 50 shows the initial setup programmer 1200 with a custom programmer 1100 fit into the depression 1210 with the two contact pins 1212 extending upwards through the access holes 1136 in the bottom of the instant programmer 300.

FIG. 51 is a schematic that shows circuitry included in the initial setup programmer 1200. The initial setup programmer includes a microcontroller (NEC  $\mu$ PD7530x) 1214, a liquid crystal display 1216, a keypad 1218, static

1 random access memory (static RAM) 1220, computer port 1222 and programming pins 1224. Local channel tables can be transferred from a computer to the initial setup programmer 1200 and stored in static RAM 1220.

5 FIG. 52 is a schematic showing the data transfer connection between a personal computer 1226 and initial setup programmer 1200. Local channel table data is output from personal computer 1226 through a serial RS-232 port with +12 and -12 volt signals. The +12 and -12 volt signals are transformed to TTL compatible 0 and 5 volt signals by level shifter 1228 which are input into microcontroller 1214. Level shifter 1228 can be either external or internal to  
10 initial setup programmer 1200.

Alternatively, local channel table data can be transferred to the initial setup programmer 1200 by audio signals carried over telephone lines. Further, local channel tables may be entered into the initial setup programmer through keyboard 1202 in the same manner used to program this information into either  
15 instant programmers 300 or custom programmers 1100.

Included in keyboard 1202 are "SEND CLK", "SEND CH", "SEND CAB" and "SEND VCR", which set the clock, download the local channel table, select the protocol for the cable box brand and model and select the protocol for the VCR brand and model, respectively when they are pressed. If the information  
20 is successfully transferred to the instant programmer 300 or custom programmer 1100 connected to the initial setup programmer 1200, display 1204 displays the message "Tr OK", otherwise the message "Tr Err" is displayed on display 1204.

Data is transferred to instant programmer 300 and custom programmer 1100 through the two contact pins 1212. The first of these pins is the ground pin. The second pin connects with test point 392 as shown in FIG. 22. Test point 392 is connected to both an interrupt pin and one input/output (I/O) pin of microcomputer 380. The two pins are tied together with an open collector method so that both input and output can be accomplished with one pin. The  
25 two contact pins 1212 connect to the same functional pins of the microcomputer 1150 of the custom programmer 1100. Data is transferred serially through these pins at a 4800 baud rate using TTL voltage levels. The instant programmer 300 and custom programmer 1100 return a low pulse of a predetermined length to the initial setup programmer 1200 when they have received all of transferred data.  
30

35 The invention as shown in the preferred embodiments of the custom programmer 1100 and the initial setup programmer 1200 can be readily included within televisions, video cassette recorders, cable boxes, or satellite receivers.

1 It would not be complicated to embed either the custom programmer 1100 or the initial setup programmer 1200 in televisions, video cassette recorders, cable boxes, and satellite receivers by adding suitable cabling or other transmission means between various video devices being used.

5 Another embodiment of the invention is the custom controller 1300 shown in FIGS. 53-58. The custom controller contains the same circuitry and performs the same functions as the custom programmer 1100, but also performs the functions of a complete universal remote control that can be setup automatically. The custom controller includes on its main control surface 1302 and its auxiliary control surface 1304, buttons that perform the same functions as buttons 1102-1112, 1156 of the custom programmer, a display 1306 that performs the same functions as display 1134, 1154 and IR transmitters 1314 which perform the same functions as IR transmitters 1131, 1158. The custom controller can also be equipped with a lid (not shown) that covers hidden keys (not shown) used to setup the custom controller like lid 1114 on the custom programmer 1100 and lid 316 and keys 316-330 on the instant programmer 300. The keys under the lid could include SAVE, ENTER, CLOCK, CH, ADD TIME, VCR, CABLE and TEST keys like the instant programmer and the custom programmer.

20 The custom controller includes a microphone 1308, which performs the same functions as microphone 1140 of the custom programmer and is accessible through the microphone access hole 1309. Through the microphone, the custom controller is programmed with all of the setup information needed to function as an instant or custom programmer (i.e., channel map, current time of day, 25 model/brand of cable box and VCR). Alternatively, the custom controller can be programmed by the initial setup programmer 1200 shown in FIGS. 45-47 and 49-51 in the identical manner described above in connection with these figures for the instant and custom programmers. Accordingly, the custom controller includes access holes 1310 through which contact can be made with the contact pins 1212 of the setup programmer 1200.

30 Custom controller 1300 also includes additional buttons on its control surfaces 1302 and 1304 that can be used to operate any home electronic device that can be controlled by an infrared remote control. These standard infrared remote controls work by transmitting different IR codes for each different 35 function to be performed by the device being controlled. Each button of the custom controller triggers the transmission of an IR code that would ordinarily be transmitted by another remote control. The actual make up of these IR codes

1        used to control the various home electronic equipment are described in more  
detail in United States Patent No. 4,623,887 to Welles, II which is hereby  
incorporated by reference.

5        Most of the time, the custom controller will be used to control televisions,  
VCRs, cable boxes, satellite receivers and hi-fi audio equipment. It is noted that  
both the instant programmer 300 and the custom programmer 1100 already  
functioned as universal remote controllers with respect to video recorders, cable  
boxes, televisions and satellite receivers as they can control diverse brands and  
10       models of these devices. However, the instant and custom programmers only  
use their universal remote features to change or select channels on cable boxes,  
video recorders, televisions and satellite receivers, begin and end recording by  
video recorders and turning the power on any of these devices on and off.  
Nonetheless, the schematic of the custom controller will be the same as the  
schematics of the custom programmer shown in FIGS. 43 and 44 except that the  
15       custom controller includes a keypad (see 1156) with more buttons and the size  
requirements for the ROM and RAM in the microcomputer (see 1150) are greater  
than in the custom programmer. FIGS. 58 and 59 show block diagram  
schematics for two alternate embodiments of the custom controller. It is noted  
these two schematics contain the same basic components, but the utilization and  
20       minimum size of the RAMs 1324 and 1330 and ROMs 1326, 1332 are different.

The custom controller's complete universal remote feature operates as  
follows. Each button on the keyboard 1320, which is mounted on control  
surfaces 1302, 1304 of the custom controller, is hard wired with a button code  
or a memory address, which is generated each time the button is pressed. The  
25       microcomputer 1322 receives the code or address generated by the pressed  
button and, if the button generates a code, consults a look-up table to retrieve  
an address for the button code. This look-up table, as well as the instructions  
that control the operation of the microprocessor are stored in ROM 1326 and  
1332.

30       In the embodiment of FIG. 58, the microprocessor retrieves an IR code  
from RAM 1324 at the address derived from the pressed button. In this  
embodiment, the minimum size for the ROM is very small as the ROM only needs  
to store the button code look-up table and microprocessor instructions.  
However, the size of the RAM needs to be large enough to store an IR code for  
35       each button on the keyboard.

In the embodiment of FIG. 59, the microprocessor consults a look-up table  
in RAM 1330 which contains address to ROM 1332, which contains the actual

1 IR codes. The ROM address is retrieved from RAM at the address derived from  
the pressed button on keyboard 1320. The IR code is then retrieved from ROM  
at the address retrieved from RAM. This embodiment allows the ROM to be  
preprogrammed with the IR codes for a large number of home electronic devices.  
5 This increases the minimum size of the ROM substantially, but reduces the  
minimum size of the RAM because ROM addresses are generally shorter than IR  
codes.

10 In both the embodiments of FIG. 58 and 59, the IR code retrieved from  
either ROM or RAM is sent by the microprocessor to IR transmitters 1328 and  
is transmitted.

Before the custom controller can be used as a complete universal remote  
control, it must be programmed with the IR codes for the functions and the  
brand and models of home electronic equipment it is going to control.  
Traditionally this has been done in two different ways. First, the custom  
15 controller can "learn" the IR codes for the products that it is to control from the  
remote controls that come with each product. The custom controller would then  
also include an IR receiver (not shown) that would receive IR codes from other  
remote controls and store these codes and which button on the custom  
controller each code is associated with into RAM. This type of "learning"  
20 controller usually employs the schematic of FIG. 58. The second traditional  
programming method involves providing a ROM that contains the IR codes for  
most functions of most brands and models of home electronic equipment. The  
user then enters into the custom controller what brand/model of each type of  
home electronic device that the user plans to use the custom controller with. In  
25 this method, for each brand and model of home electronic equipment, the  
custom controller will also include in ROM the associations between the IR codes  
for the equipment and the keys on the custom controller that will trigger the  
sending of the IR codes. A controller utilizing this second programming method  
usually employs the schematic of FIG. 59.

30 In an alternate embodiment, the custom controller can be programmed by  
either of both of these methods. IR codes that are "learned" from other remote  
controllers are stored in RAM 1324 shown in FIG. 58. Alternatively, ROM 1332  
shown in FIG. 1332 includes IR codes for most VCRs, cable boxes, satellite  
receivers, televisions and stereo components and the ability to program which  
35 brand/model of these device he or she is using. In yet another embodiment, the  
embodiments shown in FIGS. 58 and 59 can be combined by including a flag bit  
in the data stored in RAM 1324 or 1330. If the flag bit is set, the rest of the

1 data at that address is a ROM address which points to the location of the IR code in ROM 1332. If the flag bit is not set, the rest of the data at that address contains actual IR code data.

5 In the preferred embodiment of FIGS. 53-60, though, IR codes are programmed into the memory of the custom controller through the microphone 1308 that is used for the setup of the channel map, cable box and VCR brand/model and the current time of day. Using the process shown in FIG. 60, a process similar to that described above in connection with the custom programmer 1100, in block 1340, the user calls either a special phone number  
10 which could be a toll-free 800 number, a pay-per-minute 900 number, or a standard telephone number with standard toll charges applying. In block 1342, the consumer speaks on the telephone to a customer service representative (representative) located at a remote site who orally inquires from the consumer the information regarding the brand and model of each home electronic device  
15 with which the consumer wants to use custom controller. In blocks 1346 and 1348, the consumer also has the opportunity to tell the representative which functions each button of the control surfaces 1302 and 1304 is to perform. In block 1350, the representative enters this information into a computer at the remote site. If the consumer does not have preferences regarding which button  
20 of the custom controller is used to perform which functions, in block 1352, the representative does not enter any preferences into the computer and the computer relies on default associations between the buttons and functions that are previously stored in the computer.

Once this information has been entered into the computer, in block 1354  
25 the computer programs the custom programmer in at least two different ways, depending on whether the embodiment of FIG. 58 or 59 is used. If the embodiment of FIG. 58 is used, the computer downloads, through microphone assembly 1334 in either manner described above in connection with the custom programmer and shown in FIGS. 43 and 44, all of the necessary IR codes into  
30 RAM 1324 at the addresses associated with the buttons on the keyboard 1320 according to the consumer's expressed wishes. If this method is used, no IR codes need be stored in the ROM of the custom controller when it is manufactured.

If the embodiment of FIG. 59 is used, the ROM 1332 installed into the  
35 custom controller at manufacture is programmed with the IR codes of many different brands, models and types of home electronic devices. In this case, the computer downloads, through microphone assembly 1334, the addresses of the

1 ROM for all of the necessary IR codes into RAM 1330 instead of downloading the IR codes themselves.

5 In an alternative embodiment the ROM 1332 contains default associations between IR codes and buttons of the custom controller, so that these associations need not be downloaded unless the consumer has requested associations between buttons and IR codes that are different from the default associations. This method reduces the amount of data that needs to be sent over the telephone lines from the remote site to the custom controller, but can increase the size and cost of the ROM installed in the custom controller. In the 10 rare case where the IR codes for the device that the consumer wants to control are not included in the ROM, the computer would just download the IR codes themselves for that device as in the first programming method described above with reference to FIG. 58.

15 It is noted above that in either of the embodiments shown in FIGS. 58 and 59, the microphone and decoding assemblies from either FIG. 43 or FIG. 44 may be used. Preferably, the microphone and decoding assembly in FIG. 44 is used as it is less expensive than the assembly in FIG. 43 that uses a DTMF decoder 1166. The system shown in FIG. 44 utilizes just two single frequency signals rather than many dual frequency signals as in a DTMF system. The first 20 signal, a tone of approximately 3000 Hz, is used to signify a binary "one" and the second signal, a tone of approximately 500 Hz, is used to signify "zero." Since a 500 Hz signal is being used in this embodiment, the bandwidth of the 1000-5000 Hz high pass filter 1168 from FIG. 44 will have to be broadened to include 500 Hz when included in the microphone and decoder assembly 1334.

25 A series of these two tones are transmitted over the telephone line, representing a binary series. A short period of no signal is included between each tone in the series of tones so that two consecutive 500 Hz or two consecutive 3000 Hz signals are interpreted as two sequential signals and not one long signal. In an alternative embodiment, the series of signal tones are sent 30 at a predetermined clock speed.

A decoder (not shown) is included between the microphone assembly 1334 and the microprocessor 1322 that converts the 3000 Hz signals to high electrical signals and converts the 500 Hz signals to low electrical signals that are sent to a serial input into the microprocessor. A clock signal is 35 simultaneously sent to the microprocessor with each high or low signal.

1           Alternatively, the initial setup programmer 1200 could be used to perform  
the IR code programming of the custom controller 1300 instead of using the  
microphone/telephone interface.

5           Another embodiment, shown in FIGS. 61-62 is an alternative embodiment  
to the embodiment shown in FIG. 33. An initial setup routine must be performed  
on the VCR in the embodiment in FIG. 33 similar to that which must be  
performed on the instant programmer 300. This consists of entering, into the  
VCR, the local channel map, the current time and an identification of the cable  
10 box, television or satellite receiver that is to be controlled by the VCR. In the  
embodiment of FIG. 33, this initial setup is performed manually by the user in the  
same manner as for the instant programmer by pressing a series of keys on  
either the VCR itself or the television remote control 956 used to control VCR.  
In this embodiment shown in FIG. 61, the television remote control from FIG. 33  
is replaced with an auto-programming VCR remote control 1400 ("VCR remote").  
15 The VCR remote includes a CPU 1402, RAM 1404, ROM 1406, keyboard 1408  
and an IR transmitter 1410 that are typical for IR remote control units. Further,  
the VCR remote includes a microphone 1412 and an audio signal decoder 1414.  
The microphone and decoder can be either of the embodiments 1166 or  
1168-1170 shown in FIGS. 43 and 44. As with the custom controller described  
20 above, however, the decoders 1168-1170 in FIG. 44 and 1334 in FIGS. 58-59  
are preferred as the more economical embodiment.

In the preferred embodiment, the alternative VCR remote 1400 is also a  
universal remote such as custom controller 1300 with all of the structure and  
functions of the custom controller. Thus, the VCR remote is capable of  
25 controlling the cable box 1428, VCR 1416, television 1432 and any other  
auxiliary home electronic equipment that is IR remote controllable 1434.

A significant advantage of the VCR remote control is that the data  
required to be entered into the VCR 1416 for the initial setup can initially be  
downloaded from a remote site by telephone to the VCR remote control. To do  
30 this, the consumer calls the remote site in the telephone, orally gives the  
information necessary to perform the initial setup to a person at the remote site.  
The person at the remote site then instructs the consumer to place the  
microphone of the VCR remote to the telephone earpiece and the initial setup is  
downloaded. Thereafter, the user easily causes the data to be downloaded by  
35 IR transmission, from the VCR remote control to the VCR itself by pressing a  
"send" key or a "send" sequence of keys. The VCR receives the initial setup

1 data, stores it in its memory 1420 and then is ready to be used as an instant programmer.

5 In an alternative embodiment, shown in FIG. 63, the structural elements of the custom programmer 1100 shown in FIGS. 40-44, including a microphone 1450 and decoding assembly 1452, are embedded within a VCR 1454 instead of embedding the structural elements of the instant programmer 300 into the VCR as shown in FIG. 33. In this embodiment, the user would hold the earpiece of their telephone 1456 to the microphone embedded in the VCR to download the initial setup data directly from the remote site into the VCR. The difficulty with this embodiment is that often a user's VCR and telephone are not located close enough together to position the telephone earpiece near the VCR. Further, correction of this problem, which would involve adding an extension cord to the telephone or disconnecting and relocating the VCR nearer the telephone are not convenient.

15 In another embodiment, shown in FIG. 64, the microphone in the VCR with custom programmer embedded is replaced with a modular phone jack 1458 that leads directly to the decoder assembly 1452 in the VCR. A standard telephone line 1460 would then connect the VCR to a modular T-connector 1462 so that both the VCR and an independent telephone 1464 are connected to the telephone line 1466. The consumer then uses the telephone to call and talk to the remote site, but the data is transmitted directly to the VCR. The transfer of data by this method may be more accurate than transmission by audible tones. However, this embodiment suffers from the same problem of the proximity of the consumer's phone outlets to the VCR.

25 With the embodiment shown in FIG. 61, though, the proximity of the VCR to a consumer's telephone or telephone jack are not important. The consumer simply carries the remote to his or her phone and gets the initial setup data downloaded into the VCR remote. The consumer then carries the remote to a location near the VCR and downloads the initial setup data to the VCR.

30 Another embodiment, shown in FIG. 65, is to install a modular jack 1466 into the VCR remote 1400. In this embodiment, the VCR remote is connected to the telephone by a T-connector 1468 and operates in the same way as the VCR with a built-in modular jack described above and shown in FIG. 64 except that after the initial setup data is transferred to the VCR remote, the VCR remote is placed near the VCR and the initial setup data is downloaded by IR transmission to the VCR. One advantage that this embodiment has over the VCR with a built-in modular jack is that the VCR remote can be taken to the

1 telephone whereas the VCR may be located far from the telephone. It is also  
possible to add a DTMF generator to the VCR remote so that the keypad 1408  
of the VCR remote can be used to dial the telephone number of the remote site.  
Alternatively, telephone numbers for the remote site are stored in the memory  
5 of the VCR remote so that the consumer may dial the remote site by pressing a  
minimum number of keys.

The details of the operation of the VCR remote are as follows. In the first  
step, shown in block 1440 of FIG. 62, the consumer places a telephone call on  
either an 800, 900 or normal toll call line to a customer service representative.  
10 In block 1442, the representative inquires from the consumer information  
necessary to perform the initial setup, such as the consumer's ZIP code or the  
name of the consumer's cable company, the television guide that consumer uses,  
the brand and model of the consumer's cable box (it is sometimes possible to  
deduce this data from the ZIP code or cable company name data) and the brand  
15 and model of the consumer's VCR. As with the initial setup of the custom  
programmer, the channel map and cable box IR codes can be determined from  
this data. If the VCR remote control is also a universal remote control, the  
representative inquires as to the brands and models of any other IR controllable  
home electronic equipment that the consumer may wish to control with the VCR  
20 remote control.

Once the channel map and IR code data to be downloaded have been  
identified in block 1442, the initial setup data, including the channel map,  
IR code data and the current time, including the date, is downloaded over the  
telephone line to the VCR remote control. In the preferred embodiment, the  
25 initial setup data is generated by a computer at or connected to the  
representative's location, transmitted over telephone lines in the form of audio  
signals, received by the VCR remote control's microphone or modular phone jack  
and decoder, and stored into RAM 1404 by CPU 1402.

In block 1448, the consumer presses a "send" key or a sequence of keys  
30 that triggers the transmission of the initial setup data through the IR transmitter  
to the VCR's IR receiver. If the VCR remote control is a universal remote, the  
IR codes for IR controllable devices other than the cable box are preferably not  
be transmitted to the VCR as they are used by the VCR remote control itself, not  
the VCR. The data is stored by the VCR's CPU into the VCR's RAM.

35 In an alternative embodiment, the VCR remote control's IR transmitter is  
not a multi-directional or wide angle IR transmitter. The more expensive multi-  
directional or wide angle IR transmitters are not necessary because the

1 IR transmitter is not used to transmit IR signals when the VCR remote control is set on a table or on top of the cable box or VCR.

In any case, in the preferred embodiment, a multi-directional or wide angle IR transmitter is retained to increase the likelihood of the successful downloading of all of the initial setup data. Although the quantity of the initial setup data is not tremendous, it is substantial. Thus, an uninterrupted IR stream of a significant duration is required to reach the VCR from the VCR remote control. The more diverse the radiation of IR signals is, the more likely it is that all of a stream of IR signals will reach the IR receiver in the VCR, either directly or by reflection.

For preexisting VCRs with a built-in instant programmer and IR transmitter that were made before the present VCR remote control, that can also have their initial setup performed through the use of a remote control, the VCR remote control can be programmed, either with a program stored in ROM at manufacture or by telephone into RAM, to use the preexisting VCRs own protocol for initial setup using a remote control. In other words, the VCR remote control is programmed to mimic a consumer using the VCR's original remote control to perform the initial setup.

In VCRs designed specifically for use with the VCR remote control, a special protocol, designed to reduce the length of the IR transmission sent to the VCR is used. In an alternative embodiment, part of this special protocol includes using a receipt confirmation signal combined with known error detection and/or error correction schemes to assure the reception of the entire stream of initial setup data by the VCR. Known error detection schemes that can be used include using a parity check bit in every byte of data and embedding a code at some point in the data stream that indicates the length of the entire data stream. The use of these and other known error detection and correction schemes allows the VCR to verify whether the complete stream of error free initial setup data was received. If it is verified that the data received is correct and complete, the VCR can produce an indication, either audio or visual, that the initial setup data was successfully received. If it is not verified that the data received is correct and complete, the VCR either gives no indication or produces a second indication to indicate an unsuccessful transmission. Upon an unsuccessful transmission, the consumer adjusts the position of the VCR remote control relative to the VCR and retransmits the initial setup data.

Another alternative is to provide modular telephone jacks in both the VCR and the VCR remote control for downloading the initial setup data from the VCR

1 remote control to the VCR. This embodiment provides for more error free  
transmission of the initial setup data, but forces the consumer to connect,  
disconnect and store the cable that links the VCR remote control and the VCR.

5 Yet another alternative is to include in the VCR a microphone and decoder  
assembly similar to the microphone and decoder assembly 1412-1414 in the  
VCR remote control. An encoder and speaker (not shown) are then added to the  
VCR remote control. With this alternative embodiment the initial setup data is  
10 transmitted from the VCR remote control to the VCR using the same type of  
audio signals as used to download the initial setup data over the telephone lines  
to the VCR remote control. When the consumer is ready to transmit the initial  
setup data from the VCR remote control to the VCR, he or she simply holds up  
the speaker of the VCR remote control to the microphone of the VCR and  
presses the keys necessary to trigger transmission. In the preferred embodiment  
of this alternative, with current speaker and microphone technology, the speaker  
15 and microphone on the VCR remote control can be combined into a single  
microphone/speaker component.

In the downloading process of blocks 1446-1452, the channel map data  
and IR code data for the VCR is transmitted and stored into the RAM of the VCR  
remote control first. Thereafter the data is retransmitted to the VCR and stored  
20 into the RAM of the VCR. After transmission to the VCR of the channel map  
data and IR code data for the VCR is completed, the channel map and IR code  
data for the VCR is erased from the RAM in the VCR remote control. If IR code  
data for use by the VCR remote itself is initially downloaded with the channel  
map data and IR code data for the VCR, this data is, of course, not erased from  
25 the RAM in the VCR remote control.

As described above in reference to the custom controller 1300, shown in  
FIGS. 53-60 and particularly FIGS. 58 and 59, the IR codes for control of the  
cable box and other remote controllable electronic equipment that are  
downloaded over a telephone line to the video recorder, either directly or via a  
30 VCR remote, are stored in different ways in different alternative embodiments.  
Thus, IR codes for numerous cable boxes and other devices can be stored in the  
ROMs of the video recorder and the VCR remote with the addresses of the IR  
codes for a particular cable box or other device being downloaded to the RAM  
of the video recorder or VCR remote. Alternatively, the IR codes themselves can  
35 be downloaded to the RAM of the video recorder or VCR remote.

The invention as shown in the various embodiments of the VCR  
remote 1400 can readily be used with televisions, cable boxes, satellite receivers

1 or other audio-visual components that contain remote control receivers and/or  
transmitters. The only differences in operation in these alternate configurations  
are the IR codes and downloading protocols that the VCR remote uses.  
However, the VCR remote as described above is capable of having these codes  
5 and protocols downloaded by telephone along with the initial setup data.

Another embodiment is shown in FIG. 66. This embodiment is an  
alternative to the system shown in FIG. 33 that automatically controls the  
recording by a VCR 1500 and the channel selection of a cable box (and/or  
satellite receiver) 1501 utilizing a cable box programmer 1510. The cable box  
10 is interchangeable with a satellite receiver or any other converter/tuner because  
all operate as television signal converters and tuners that receive many television  
signals on many different frequencies and select and output one of these  
television signals on a single selected frequency. The only practical difference  
between most cable boxes and satellite receivers are the number of television  
15 signals received and the frequencies on which they are broadcast.

Like the system shown in FIG. 33, in the system shown in FIG. 66, the  
channel, date, time-of-day and length of programs ("CDTL information") to be  
automatically recorded are entered into a VCR 1500. This programming  
information may be entered using a keyboard on the VCR (not shown), the VCR's  
20 remote control 1502 or any other entry means. The programming information  
can be entered in a variety of formats, including the entering information directly,  
using on-screen programming techniques or entering a G-code that is  
representative but compressed in length from the CDTL information. If the CDTL  
information is entered in a G-code format, the VCR CPU 1504, executing a  
25 program stored in the VCR memory 1506, decodes the G-code into a set of  
separate CDTL commands.

The VCR CPU 1506 stores the date, time and length commands  
("DTL information" or "recorder subset") from the set of CDTL commands in a  
VCR stack memory implemented in the VCR memory 1506 in a manner identical  
30 to that of instant programmer 300, custom programmer 1100 and custom  
controller 1300, except that the channel command need not be stored.  
However, in the preferred embodiment, the channel command is also stored in  
the VCR stack memory because, even though it is not needed to control the  
VCR, it is needed for display when a user wishes to review the television  
35 programs that are currently stored in the VCR stack memory. The CPU then  
immediately transmits the channel, date and time-of-day commands

1 ("CDT information" or "cable subsets") from the CDTL information through a VCR IR transmitter 1508 to a separate cable box programmer 1510.

5 The cable box programmer includes an IR receiver 1512, a cable programmer CPU 1514, a cable programmer memory 1516, a cable programmer clock 1518 and a cable IR transmitter 1520. The cable programmer CPU 1514 receives the CDT information transmitted by the VCR through the IR receiver 1512. The IR codes used by the VCR to transmit the CDT information are unique to the cable programmer and are not understood by the cable box 1501. The CDT information is stored by the cable programmer CPU into a cable stack memory implemented in cable programmer memory 1516, sorted by date and time in the same manner as is done in the VCR stack memory.

10 As can be done with instant programmer 300, custom programmer 1100 and custom controller 1300, CDTL information for a television program entered into the VCR/cable programmer can be deleted. In the case of the VCR/cable programmer, a command that a program should be deleted from the program stack is entered into the VCR either directly or through a remote control. This delete command may include reentering the CDTL information for the program or selecting the program from a review display of the programs stored in the VCR stack memory. The VCR CPU searches the VCR stack memory for the set of CDTL information to be deleted and deletes this set from the VCR stack memory. The VCR CPU then sends a deleted signal followed by the CDT information for the program being deleted to the cable programmer. The cable programmer CPU then searches the cable stack memory for this cable subset of CDT information and deletes this cable subset from the cable stack memory.

25 Other than this initial communication of the CDT information from the VCR to the cable box programmer at the time corresponding CDTL information is entered into the VCR, the VCR and the cable box programmer act independently of each other. The cable box programmer sends channel selection commands to the cable box 1501 according to the CDT information stored in the cable stack memory and the output of the cable programmer clock 1518. The VCR supplies record on and off commands to its recording circuits 1522 according to the DTL information in the VCR stack memory and the output of the VCR clock 1524. The only other communication between the VCR and the cable box programmer involves the periodic coordination of the VCR clock and the cable control clock. This coordination begins by the VCR transmitting, through the VCR IR transmitter, a coordinate clock command and the current time

1 according to the VCR clock 1524. Whenever the VCR transmits the coordinate  
clocks command, the cable programmer CPU 1514 receives the command and  
the current time according to the VCR clock through the IR receiver 1512. Using  
5 the received current time according to the VCR clock, the cable programmer CPU  
resets the cable programmer clock 1518 to match the current time according to  
the VCR clock. Depending on the accuracy of the VCR clock and the cable  
programmer clock, the periodic coordination of the VCR clock and the cable  
programmer clock may need to be performed several times a day to once a  
10 month or even longer. Once an adequate rate is determined, the VCR CPU is  
programmed to transmit the coordination command and time according to the  
adequate rate.

In an alternative, preferred embodiment, coordinate clock commands are  
sent from the VCR to the cable programmer every time CDT information is  
transmitted from the VCR to the cable programmer. As described above,  
15 CDT information is transmitted each time CDTL information is entered into the  
VCR by a user. In this embodiment, periodic transmission of the coordinate  
clock commands is not necessary because the only time that it is important to  
have the clocks coordinated is when CDTL information is being programmed,  
which is exactly the time when coordinate clock commands are sent in this  
20 embodiment.

Once the VCR 1500 is programmed with at least one set of CDTL  
information, the VCR CPU will periodically compare the date and time commands  
from the DTL information in the top location of the VCR stack memory with the  
current time according to the VCR clock. When these two values are the same  
25 or are within a certain range of each other, the CPU issues a command to the  
recording circuits of the VCR to begin recording. When the time command from  
the top of the VCR stack memory added to the length command from the top of  
the stack is the same or are within a certain range of the current time according  
to the VCR clock, the VCR CPU issues a command to the recording circuits of  
30 the VCR to stop recording. The DTL information at the top location of the  
VCR stack memory is then discarded from the stack.

Once the cable box programmer is programmed with at least one set of  
CDT information, the cable programmer CPU 1514 will periodically compare the  
date and time command from the CDT information in the top location of the  
35 cable stack memory with the current time according to the cable programmer  
clock. When these two values are the same or are within a certain range of each  
other, the CPU transmits a channel select command, through the cable

1 programmer IR transmitter 1520, to the cable box 1501 which, in turn, changes the channel of the cable box to the channel that corresponds to the channel command stored in the top location of the stack. The CDT information at the top location of the cable stack memory is then discarded from the stack.

5 Even though the operation of the cable box programmer and the VCR as described above is completely independent, if the VCR clock and the cable control clock are even roughly coordinated, the channel will be changed on the cable box at approximately the same time that the VCR begins recording.

10 The cable box programmer requires some of the same auxiliary data to perform its functions properly that is also required by the instant programmer 300, custom programmer 1100 and custom controller 1300. More specifically, the cable box programmer must be programmed with the IR codes for controlling the particular cable box it is to be controlling and cable channel map information for the local cable system. The IR codes for controlling a particular cable box  
15 may either be prestored in the cable programmer memory 1516 for a number of cable boxes and a code selecting among these cable boxes is provided or the IR codes themselves are provided once the particular cable box to be used is identified. All of this auxiliary data may be programmed directly into the VCR 1500 in the same manner that this information is entered into the instant  
20 programmer 300, the custom programmer 1100, the custom controller 1300 or the VCR 991 shown in FIG. 33. The data is then transmitted from the VCR to the cable box programmer through VCR IR transmitter 1508 and IR receiver 1512, received by the cable programmer CPU 1514 and stored in the cable programmer memory 1516.

25 The cable box programmer is ideally battery powered and contained in a small box without any external controls, having an IR receiver and an wide angle IR transmitter as the only external features of the box. The box is set on or near the cable box and within the general vicinity of the VCR. Alternatively, though, the cable box programmer can be incorporated into otherwise standard cable box  
30 remote controls, VCR remote controls and universal remote controls. Another alternative is to incorporate some or all of the features of instant programmer 300, custom programmer 1100 and custom controller 1300, including the ability to download auxiliary information over a phone line directly to the cable programmer. Yet another alternative is to include the features of receiving and  
35 retransmitting IR codes and other setup data of VCR remote 1400 into the cable programmer 1510.

1           An alternative design of the system shown in FIG. 66 is shown in FIG. 67.  
This system includes a programmable VCR 1600 that controls the channel  
selection of a cable box 1601. The VCR 1600 includes a VCR control  
CPU 1604, a VCR control memory 1606, a cable control CPU 1614, a cable  
5   control memory 1616, a cable control clock 1618, a cable IR transmitter 1620,  
recording circuits 1622 and a VCR control clock 1624. The VCR control  
CPU 1604, VCR control memory 1606, cable control CPU 1614, cable control  
memory 1616, cable control clock 1618, cable IR transmitter 1620, recording  
circuits 1622 and VCR control clock 1624 operate in the same manner as the  
10   VCR CPU 1504, VCR memory 1506, cable programmer CPU 1514, cable  
programmer memory 1516, cable programmer clock 1518, cable IR transmitter  
1520, recording circuits 1522 and VCR clock 1524, respectively, except that  
any data and commands transmitted by the VCR CPU 1506, through VCR  
IR transmitter 1508, received by IR receiver 1512, and to cable programmer  
15   CPU 1514 are instead sent directly from VCR control CPU 1606 to cable control  
CPU 1614. In this alternative, all of the components housed separately from the  
VCR in the cable programmer as shown in FIG. 66 are instead housed inside the  
VCR. Further, these components can then share the same power supply and  
even the same circuit board.

20           Another alternative the systems shown in FIGS. 66 and 67 is the system  
shown in FIG. 68. Like the system shown in FIG. 66, the system shown in  
FIG. 68 automatically controls the recording by a VCR 1650 and the channel  
selection of a cable box 1652 utilizing a simplified cable box programmer 1654.  
Again, like the system shown in FIG. 33, in the system shown in FIG. 68, the  
25   channel, date, time-of-day and length of the programs to be automatically  
programmed ("CDTL information") are entered into a VCR 1650. This  
programming information may be entered using in the same formats and through  
the same means as with VCR 1500 shown in FIG. 66. The CDTL information  
received by the VCR is stored in a programming timer 1656. The programming  
30   timer contains a CPU and a memory and performs the same functions as the  
instant programmer 300, custom programmer 1100, custom controller 1300 and  
the VCR 991 shown in FIG. 33 except for its changing of the channel on the  
cable box. Instead of transmitting a channel select command directly to the  
cable box using IR codes that the cable box recognizes at the time recording by  
35   the VCR is to begin, an IR trigger signal is sent to the simplified cable  
programmer 1654 a preset amount of time before recording is to begin. The  
preset amount of time can be relatively short, such a minute or two.

1           The IR trigger signal, which is not meaningful to the cable box, is  
transmitted from VCR IR transmitter 1658 to IR receiver 1660. The IR trigger  
signal contains in it data representative of the channel to be tuned on the cable  
box. Alternatively, the IR trigger signal contains coded information for the  
5       IR codes to tune the cable box to the correct channel.

          When the IR trigger signal is received by the simplified cable programmer,  
a countdown timer 1662 begins timing the period of the preset amount of time  
before recording is scheduled to begin. When the countdown timer indicates that  
the preset amount of time has elapsed or will elapse within several seconds, a  
10       channel selection IR command is transmitted from a cable IR transmitter 1664  
to the cable box 1652. If the IR trigger signal included only the channel number  
to be tuned, the simplified cable programmer would have to retrieve the  
appropriate cable box IR codes to tune that channel from memory (not shown)  
in the simplified cable programmer. If the IR trigger signal includes coded IR  
15       cable box codes to tune the correct channel on the cable box, the simplified  
cable programmer would simply utilize a decoding circuit (not shown) to decode  
the IR cable box codes and transmit the decoded IR codes.

          Another alternative design of the system shown in FIG. 66 is shown in  
FIG. 69. This system includes a programmable VCR 1500 that programs a  
20       programmable cable box 1701. The VCR 1500 includes VCR control CPU 1504,  
VCR control memory 1506, VCR IR transmitter 1508, recording circuits 1522  
and VCR control clock 1524. The programmable cable box 1701 includes an  
IR receiver 1712, a cable programmer CPU 1714, a cable control memory 1716,  
a cable programmer clock 1718 and tuning circuits 1726. The IR receiver 1712,  
25       cable programmer CPU 1714, cable control memory 1716 and cable control  
clock 1718 operate in the same manner as the IR receiver 1512, cable  
programmer CPU 1514, cable programmer memory 1516 and cable programmer  
clock 1518, respectively, except that any data and commands transmitted by the  
cable control CPU 1714, through cable programmer IR transmitter 1520, and  
30       received and executed by cable box 1501 are instead sent directly from the cable  
programmer CPU 1714 to the tuning circuits 1726 in the programmable cable  
box 1701. In this alternative, all of the components housed separately from the  
VCR and the cable box in the cable programmer as shown in FIG. 66 are instead  
housed inside the cable box. Further, these component can then share the same  
35       power supply and even the same circuit board with the other components of the  
cable box.

1           It is thought that the system of the auto-programming VCR remote and  
VCR with the functions of the apparatus and method using compressed codes  
for television program record scheduling of the present invention and many of its  
attendant advantages will be understood from the foregoing description and it  
5       will be apparent that various changes may be made in the form, construction and  
arrangement of the parts thereof without departing from the spirit and scope of  
the invention or sacrificing all of its material advantages, the form hereinbefore  
described being merely a preferred or exemplary embodiment thereof.

1        WHAT IS CLAIMED IS:

1.        A system for automatically recording television programs comprising:  
         a converter/tuner for receiving a plurality of television signals at different  
5        channel frequencies, selecting one among the plurality of television signals,  
         converting the selected television signal to a single channel frequency according  
         to channel select commands and supplying said single channel frequency to an  
         output;  
         a video recorder having an input coupled to the output of said  
10        converter/tuner comprising:  
             first receiving means for receiving sets of channel, date,  
             time-of-day and length commands,  
             first storing means for storing recorder subsets of said sets of  
             commands, said recorder subsets comprising date, time-of-day and length  
15        commands of said sets of commands,  
             first transmitting means for transmitting cable subsets of said sets  
             of commands, said cable subsets comprising channel, date and time-of-day  
             commands of said sets of commands,  
             means for controlling the recording of video signals according to  
20        said recorder subsets, and  
             a converter/tuner programmer comprising:  
                 second receiving means for receiving said cable subsets,  
                 second storing means for storing said cable subsets,  
                 second transmitting means for transmitting channel select  
25        commands to said converter/tuner according to said received cable subsets.
2.        The system of claim 1 wherein the converter/tuner comprises a cable box.
3.        The system of claim 1 wherein the converter/tuner comprises a satellite  
30        receiver.
4.        The system of claim 1 wherein the converter/tuner comprises said  
         converter/tuner programmer.
5.        The system of claim 1 wherein the video recorder further comprises said  
35        converter/tuner programmer.

- 1        6.     The system of claim 1 wherein the converter/tuner programmer comprises a universal remote control capable of transmitting remote control commands to a plurality of remote controllable devices.
- 5        7.     The system of claim 1 wherein said first receiving means comprise:  
         means for receiving compressed coded indications, each representative and compressed in length from, sets of channel, date, time-of-day and length commands, and  
         means for decoding and expanding said compressed coded indications into  
10       sets of individual channel, day, time-of-day and length commands.
8.     The system of claim 1 wherein:  
         said means for controlling comprise a first clock,  
         said second transmitting means comprise a second clock,  
15       said first transmitting means comprises means for transmitting the output of said first clock, and  
         said second receiving means comprises means for receiving said output of said first clock and resetting said second clock according to said output of said first clock.
- 20       9.     The system of claim 8 wherein said first transmitting means transmits the output of said first clock in sequence with said cable subsets.
10.    The system of claim 8 wherein said first transmitting means transmits the output of said first clock periodically, independent from the times of transmission of said cable subsets.
- 25       11.    The method of automatically recording television programs using a system comprising a converter/tuner with an output coupled to the input of a video recorder and a converter/tuner programmer comprising the steps of:  
30       using said converter/tuner,  
         receiving a plurality of television signals at different channel frequencies,  
         selecting one among the plurality of television signals, converting  
35       the selected television signal to a single channel frequency according to channel select commands, and  
         supplying said single channel frequency to said output;

1           using said video recorder,  
            receiving sets of channel, date, time-of-day and length commands,  
            storing recorder subsets of said sets of commands, said recorder  
subsets comprising date, time-of-day and length commands of said sets of  
5           commands,  
            transmitting cable subsets of said sets of commands, said cable  
subsets comprising channel, date and time-of-day commands of said sets of  
commands, and  
            controlling the recording of video signals according to said recorder  
10          subsets, and  
            using said converter/tuner programmer,  
            receiving said cable subsets,  
            storing said cable subsets,  
            transmitting channel select commands to said converter/tuner  
15          according to said received cable subsets.

12. The method of claim 11 wherein the step performed using said  
converter/tuner are further performed using a cable box.

20          13. The method of claim 11 wherein the steps performed using said  
converter/tuner are further performed using a satellite receiver.

14. The method of claim 11 wherein the steps performed using said  
converter/tuner are further performed using said converter/tuner programmer.  
25

15. The method of claim 11 wherein the steps performed using said video  
recorder are further performed using said converter/tuner programmer.

16. The method of claim 11 wherein the converter/tuner programmer  
30          comprises a universal remote control capable of transmitting remote control  
commands to a plurality of remote controllable devices.

35

- 1        17.    The method of claim 11 wherein said step of receiving sets of channel,  
date, time-of-day and length commands comprises the steps of:  
         receiving compressed coded indications, each representative and  
         compressed in length from, sets of channel, date, time-of-day and length  
5        commands, and  
         decoding and expanding said compressed coded indications into sets of  
individual channel, day, time-of-day and length commands.
- 10       18.    The method of claim 11 wherein:  
         said step of controlling is performed utilizing a first clock,  
         said step of transmitting channel select commands is performed utilizing  
a second clock,  
         said step of transmitting cable subsets further comprises transmitting the  
output of said first clock, and  
15       said step of receiving said cable subsets further comprises receiving said  
output of said first clock and resetting said second clock according to said output  
of said first clock.
- 20       19.    The method of claim 11 further comprising the steps of:  
         using the video recorder, periodically transmitting the output of a first  
clock, and  
         using said converter/tuner programmer, receiving the transmitted output  
of said first clock and resetting a second clock according to said output of said  
first clock,  
25       wherein said step of controlling is performed utilizing said first clock, and  
         wherein said step of transmitting channel select commands is performed  
utilizing said second clock.
- 30
- 35

- 1        20.    A system for automatically recording television programs comprising:  
         a converter/tuner for receiving a plurality of television signals at different  
         channel frequencies, selecting one among the plurality of television signals,  
         converting the selected television signal to a single channel frequency according  
5        to channel select commands and supplying said single channel frequency to an  
         output;  
         a video recorder having an input coupled to the output of said  
         converter/tuner comprising:  
         first receiving means for receiving sets of channel, date, time-of-  
10        day and length commands,  
         storing means for storing said sets of channel, date, time-of-day  
         and length commands,  
         first transmitting means for transmitting, for each of said sets of  
         commands, the channel command of such set, a predetermined amount of time  
15        before the date and time-of-day corresponding to date and time-of-day  
         commands of such set,  
         means for controlling the recording of video signals according to  
         said sets of commands, and  
         a converter/tuner programmer comprising:  
20        second receiving means for receiving said transmitted channel  
         commands,  
         second transmitting means for transmitting channel select  
         commands, derived from each of said channel commands, to said converter/tuner  
         after said predetermined amount of time has elapsed.
